Re: Juab Rural Development Agency (JRDA)  
Evaluation of Evapotranspiration Cover for Class II and Class IV Landfill  

Dear Mr. Burns:

Enclosed please find one copy of a report entitled "Evaluation of Evapotranspiration Cover for Juab Rural Development Agency Class II and Class IV Landfill." This analysis is being submitted in support of the permit renewal application for the JRDA facility located west of Nephi, Utah on Sheeplane Road, south of Highway 132.

The purpose of the study was to evaluate whether an evapotranspiration (ET) cover, using material found on adjacent property owned by JRDA, would fulfill the requirements of Utah Administrative Code R315-303-3(4) Standards for Design. The conclusion of the analysis is that use of the available material in an ET cover will achieve equivalent reduction in infiltration as compared to a standard cover.

We appreciate your review and consideration of the proposed ET cover for the JRDA facility. If there are any questions or concerns that need to be addressed, please let us know.

Sincerely,

RB&G Engineering, Inc.

Carl L. Cook, P.E.

1.0 INTRODUCTION
The Juab Rural Development Agency (JRDA) operates a landfill west of Nephi, south of Highway 132, on Sheeplane Road. The subject property is located in Section 15, Township 13 South, Range 1 West, Salt Lake Base and Meridian. JRDA owns 300 acres within this section. The location of the landfill site is presented in the Appendix as Figure 1. The landfill is permitted as a Class II and IV landfill with a standard (clay) cover design. JRDA is proposing that an evapotranspiration cover be used to close the landfill. The materials available at the site are better suited for an evapotranspiration cover than a clay cover, and evapotranspiration covers are generally able to withstand the local climatic conditions without the desiccation cracking commonly observed with clay covers.

This study evaluates whether an evapotranspiration cover, using on-site materials, will fulfill the requirements of Utah Administrative Code (UAC) R315-303-3(4) Standards for Design. The UAC states that an alternative cover such as an evapotranspiration cover must achieve an equivalent reduction in infiltration as achieved by the standard design and must provide equivalent protection from wind and water erosion as achieved by the standard design.

To demonstrate the equivalent reduction in infiltration, the expected performance of an alternative final cover design is required to be documented by the use of an appropriate mathematical model. To evaluate whether an evapotranspiration cover at the JRDA landfill meets the performance standards, RB&G Engineering collected soil samples from the landfill site, obtained hydraulic analysis of the soil samples, and performed site-specific modeling comparing the evapotranspiration cover to the standard cover.
2.0 CLIMATIC CONDITIONS

The climate data used in this analysis is derived from actual historical daily precipitation and potential evaporation data for Nephi, Utah. The analysis requires the wettest year, driest year, and average/typical year to be determined. Monthly precipitation data for 1905 to 1908 and 1942 to 2013 (all available years) was obtained from Utah State University's Utah Climate Center, GHCN (Global Historical Climatology Network), Nephi Station (Station ID USC00426135, 39.7122 degrees latitude, -111.832 degrees longitude, elevation 1563 meters/5131 feet). Seventy years included full data for every month. Table 1 and Table 2 below show a summary of precipitation for Nephi and yearly ranked precipitation.

It was determined that the maximum precipitation year was 1983. The minimum precipitation year was 1976. Precipitation patterns were evaluated, and 1987 was chosen as the year that most closely represents an average precipitation year. Data from each of these years was used in the modeling analysis as described in Section 4.0 HYDRUS Model Design of this report.
3.0 SOIL INVESTIGATION AND HYDRAULIC PROPERTIES

Soil investigations were conducted within the property owned by the JRDA (see Vicinity Map, Figure 1, in the Appendix) with the intent of locating material that would be suitable for use as the primary layer in an evapotranspiration cover system as final cover for the landfill. The investigations were conducted by excavating test pits with a backhoe and obtaining soil samples for testing. Potential borrow sites were identified by reviewing soil survey maps prepared by the U.S. Department of Agriculture, Natural Resource Conservation Service (NRCS), formerly the Soil Conservation Service. The maps are presented in Soil Survey of Fairfield-Nephi Area Utah (1984). The generalized soil information identified in the mapping is primarily provided for the purpose of land planning and potential hazard identification. The NRCS soil survey map with its accompanying legend is included for reference in the Appendix.

Soils that are most appropriate for use in evapotranspiration covers support native plant growth that can be used to reduce the moisture that may infiltrate through the cover into the underlying landfill materials. Most plants grow best in soils that have relatively balanced proportions of sand, silt and clay, such as loams, clay loams and sandy loams. Review of the generalized soils maps, shows that the area is predominated by soils with loamy characteristics.

Two areas were selected for investigation. The first is the area immediately uphill and to the south of the current landfill. The second is approximately 3,000 to 6,000 feet west of the active landfill, where there are several relatively flat areas between the surrounding hills.

A total of fourteen test pits were excavated within the two areas. The locations of the excavated test pits are shown on Figure 2 in the Appendix. It will be observed that Test pits 12-01, 12-02 and 12-03 were located at the south limits of the active landfill, and the remaining excavations were conducted in the second, westerly investigation area. Copies of the test pit logs for each excavation are attached in the Appendix.

Soil testing was conducted on samples from six of the test pits, 12-01, 12-02, 12-03, 12-04, 12-06 and 12-07. Test Pit 12-05 encountered bedrock at a depth of 6-inches below the ground surface, so no testing was performed on this material. Tests performed on the samples obtained from the identified excavations included permeability, gradations, bulk densities, and moisture content. The results of the tests are presented in the Summary of Test Data included in the Appendix. It will be observed from the results that samples from Test Pits 12-01, 12-02, 12-03 and 12-07 classify as gravelly sands with about 25% of the materials being silts and clays. These materials are generally unsuitable for evapotranspiration landfill covers.

Samples obtained from Test Pits 12-04 and 12-06 classify as loam and loam to clay-loam materials, respectively, in accordance with the NRCS soil texture criteria. These soils showed
promise for use as the primary layer in an evapotranspiration cover. The remaining seven excavations, Test Pits 14-01 through 14-07, were performed in an attempt to determine the extent of the available soil material that might be used in the landfill cover.

**Soil Hydraulic Parameters**

Soil hydraulic parameters are required to model the evapotranspiration cover. The van Genuchten-Mualem model was used for this analysis. $q_r$, $q_s$, Alpha, $n$, and $K_s$ are unsaturated hydraulic parameters used in the van Genuchten-Mualem model and are defined as follows (Simunek, 2013):

- $q_r (\theta_r)$ - residual volumetric soil water content
- $q_s (\theta_s)$ - saturated volumetric soil water content
- Alpha ($\alpha$) - van Genuchten fitting parameter, L$^{-1}$
- $n$ - van Genuchten fitting parameter, dimensionless
- $K_s$ - saturated hydraulic conductivity, LT$^{-1}$

These parameters are obtained from the soil water characteristic curve, which shows the relationship between the water content ($\theta$) and the soil water potential ($\psi$). Material from Test Pit 12-04 was analyzed by the Daniel B. Stephens and Associates, Inc., Laboratory Testing Facility in Albuquerque, New Mexico using standard hydraulic tests and methods to determine the soil water characteristic curve and associated parameters. The soil sample was tested at two levels of compaction, 82% of maximum and 88% of maximum. The full results of the hydraulic conductivity analysis are shown in the Appendix. Hydraulic parameter values reported by Stephens & Associates are shown below in Table 3.

</tr>
</tbody>
</table>

It is estimated from previous calculations in the preparation of the JRDA landfill permit, that approximately 220,000 cubic yards of material will be needed in order to provide a 30-inch evapotranspiration cover depth over the final closed landfill area. Using the depth of potentially acceptable material from the test pit excavations as shown on the logs, and an approximate area where the material is available, it is estimated that 250,000 to 300,000+ cubic yards of material can be obtained. The approximate area where the material is located is shown on Figure 3 in the Appendix.
Soil for a standard clay cover is not available on-site at the JRDA landfill. The unsaturated hydraulic parameters shown in Table 4 are provided in the HYDRUS-1D library (sourced from Carsel, 1988) as average parameters for clay (note that $K_s$ is given in cm/day below instead of cm/sec as in the reported values above). This material was chosen as the closest approximation to the clay typically used in standard covers.

UAC R315-303-3(4) requires that the final lifts of clay used to construct a standard cover design have a permeability of $1 \times 10^{-5}$ cm/sec or less. In order to match this permeability requirement, the library $K_s$ value of 4.8 cm/day for clay was changed to 0.864 cm/day (the equivalent of $1 \times 10^{-5}$ cm/sec) for the top 16 cm (approximately 6 inches) of the standard cover simulation.

Scaling factors of 1.3 for $\alpha$ and 1.1 for $n$ were applied to these laboratory-obtained parameters to account for scaling effects, hysteresis, and alteration in soil structure caused by processes such as freeze-thaw and wet-dry cycling, root growth and death, and burrowing fauna. The final values used for each model are shown in Table 5.

4.0 HYDRUS MODEL DESIGN

Model Selection
The HYDRUS-1D modeling package was selected to model the performance of the evapotranspiration cover and compare it to the performance of the standard design. Two-dimensional models are often used to model similar situations; however, the developers of the HYDRUS-1D and HYDRUS-2D packages recommend using HYDRUS-1D “for engineering problems, such as multi seasonal simulations of the recharge through landfill cover.” (HYDRUS-1D FAQ).

Three scenarios were modeled:
1) evapotranspiration cover, 82% compaction
2) evapotranspiration cover, 88% compaction
3) standard (clay) cover

The optimum compaction level for the evapotranspiration cover is approximately 85% of maximum. The 82% of maximum and 88% of maximum compaction levels were modeled to bound the optimum 85% level.

Key model input and parameters used in each of the model scenarios are described briefly as follows.

Time
The models were run for 15 years (5480 days). This includes 5 years at average rainfall conditions (1987, 14.4 inches per year), 5 years representing the driest year (1976, 6.8 inches per year), and 5 years representing the wettest year (26.5 inches per year). UAC requires the model to be run until stable with average rainfall conditions, and then to be run for 5 years representing the wettest conditions. Per instruction from the Division of Solid and Hazardous Waste, five years of the driest year (drought conditions) were added to the model to simulate a worst-case scenario that could potentially kill off the vegetation of the evapotranspiration cover and compromise its performance.

Soil Hydraulic Parameters
The van Genuchten-Mualem single porosity model was used for all model scenarios. Soil hydraulic parameters were discussed in detail in Section 3.0 Soil Investigation and Hydraulic Properties of this report. See Table 5 for a summary of the final values used for each model.
Boundary and Initial Conditions
An upper boundary condition of atmospheric with surface layer was used to allow up to 1 centimeter of water to pond at the landfill surface. A lower boundary condition of free drainage was used. A node spacing of 1 centimeter was used. The initial conditions for pressure head were set to -100 cm pressure (matric potential) at all depths in the profile. The pressure head at the surface node only was changed from -100 to 0 centimeters to simulate the boundary condition that water is ponding with no surface storage.

Transpiration Parameters
The Feddes root water uptake model was used for the evapotranspiration cover scenarios. Vegetation parameters (including root water uptake) were not included for the standard cover scenario. The local climate and growing conditions were considered in determining plant-related parameters.

The Feddes’ parameters for grass were used for the evapotranspiration cover simulations. The native vegetation at the JRDA landfill includes grasses, cedar trees, rabbitbrush, and sagebrush. When big sagebrush plants are removed prior to seeding grasses, the sagebrush often reinvades the grassed areas (Cook & Lewis, 1963, Hull & Klomp, 1974, and NRCS, 2011). Adequately maintained native shrubs and sagebrush can be appropriate vegetation for evapotranspiration covers if they are adequately maintained (Final Guidance, 2013 and Albright, 2010). These plants, particularly sagebrush, have many desirable features that may lead to better performance of the evapotranspiration cover, including greater rainfall interception, protection of grass understory, deeper and larger lateral spread of roots, and year-round transpiration from evergreen leaves. Invasive trees will be removed from the cover annually. If native grasses, shrubs, and sagebrush invade the landfill area, this will be accepted.

Climate Data
Daily temperature, precipitation, and evapotranspiration data for the years under consideration were obtained from Utah State University's Utah Climate Center, Nephi Station. Daily soil temperatures were obtained for the National Weather Service's Cooperative Network station in Salt Lake City (SLC NWSFO AP), which closely matched temperatures in Nephi. Precipitation data is discussed in more detail in Section 2.0 Climatic Conditions of this report. The total rainfall over the 15 years of the model simulation is 239 inches (606 cm). The daily potential transpiration was calculated using the leaf area index method. Calculated transpiration was subtracted from daily evapotranspiration to determine daily evaporation.

Relative humidity data for 2012-2014 was obtained from the USU Climate Center's AgMet/AgWeather network and used to calculate minimum allowed surface pressure head.
### Parameters Comparison

Model input parameters that are different for the two cover types are summarized in Table 6.

5.0 RESULTS
The results of each of the model simulations are shown in Table 7. The model output of cumulative flux through bottom of soil profile represents the cumulative infiltration through the landfill final cover. The model predicts a cumulative infiltration of 50 centimeters (19.7 inches) over 15 years for the evapotranspiration cover with 82% compaction, 33 centimeters (13.0 inches) for the evapotranspiration cover with 88% compaction, and 150 cm (59.1 inches) for the standard clay cover. Total rainfall over the 15-year model period is 606 cm (239 inches).

</tr>
</tbody>
</table>

The ideal compaction of the cover lies midway between the modeled values, at 85%. Interpolating between the results of the two models gives a cumulative bottom flux of 41.5 centimeters for an evapotranspiration cover optimally compacted to 85% of maximum.

The model results show that the evapotranspiration cover achieves a significantly greater reduction in infiltration than is achieved by the standard design.
6.0 CONCLUSION
An evapotranspiration cover, constructed using soils similar to those tested from test pit 12-04 and compacted to 82-88% of the maximum laboratory density, achieves a greater reduction in infiltration than is achieved by the standard design. In addition, the evapotranspiration cover provides equivalent protection from wind and water erosion as achieved by the standard design. Standard clay covers in the arid climate of Utah are typically prone to desiccation cracking, allowing water to infiltrate into the landfill. This phenomenon is not shown in the modeled simulation. It is often difficult to maintain vegetation on standard covers, and they become prone to wind and water erosion. The evapotranspiration cover utilizes vegetation well-suited to native conditions, or native vegetation, and it is more easily maintained, allowing the evapotranspiration cover to provide superior protection from wind and water erosion.

The proposed evapotranspiration cover, constructed of materials from the JRDA landfill site, meets the requirements for the performance of the standard clay cover and therefore satisfies the requirements of the Utah Administrative Code and the Division of Solid and Hazardous Waste.

Map Unit Descriptions

The map units delineated on the detailed soil maps in a soil survey represent the soils or miscellaneous areas in the survey area. The map unit descriptions, along with the maps, can be used to determine the composition and properties of a unit.

A map unit delineation on a soil map represents an area dominated by one or more major kinds of soil or miscellaneous areas. A map unit is identified and named according to the taxonomic classification of the dominant soils. Within a taxonomic

Re: DBS&A Laboratory Report for the RB&G Engineering JRDA Landfill Project

Dear Mr. Cook:

Enclosed is the report for the RB&G Engineering JRDA Landfill project. Please review this report and provide any comments as samples will be held for a maximum of 30 days. After 30 days samples will be returned or disposed of in an appropriate manner.

All testing results were evaluated subjectively for consistency and reasonableness, and the results appear to be reasonably representative of the material tested. However, DBS&A does not assume any responsibility for interpretations or analyses based on the data enclosed, nor can we guarantee that these data are fully representative of the undisturbed materials at the field site. We recommend that careful evaluation of these laboratory results be made for your particular application.

The testing utilized to generate the enclosed report employs methods that are standard for the industry. The results do not constitute a professional opinion by DBS&A, nor can the results affect any professional or expert opinions rendered with respect thereto by DBS&A. You have acknowledged that all the testing undertaken by us, and the report provided, constitutes mere test results using standardized methods, and cannot be used to disqualify DBS&A from rendering any professional or expert opinion, having waived any claim of conflict of interest by DBS&A.

We are pleased to provide this service to RB&G Engineering and look forward to future laboratory testing on other projects. If you have any questions about the enclosed data, please do not hesitate to call.

Sincerely,

Joleen Hines
Laboratory Supervising Manager

1. G = Gravimetric Moisture Content, VM = Volume Measurement Method, VD = Volume Displacement Method
2. CH = Constant Head Rigid Wall, FH = Falling Head Rigid Wall, FW = Falling Head Rising Tail Flexible Wall
3. HC = Hanging Column, PP = Pressure Plate, FP = Filter Paper, DPP = Dew Point Potentiometer, RH = Relative Humidity Box, EP = Effective Porosity, WHC = Water Holding Capacity, Kunsat = Calculated Unsaturated Hydraulic Conductivity
4. DS = Dry Sieve, WS = Wet Sieve, H = Hydrometer
5. F = Fine (<4.75mm), C = Coarse (>4.75mm)
Notes

Sample Receipt:
One sample arrived on April 8, 2014, in two full 1-gallon Ziploc bags, double bagged. The bags arrived in a box with packing paper and were received in good order.

Sample Preparation and Testing Notes:
Two sub-samples were prepared for initial properties testing, saturated hydraulic conductivity testing, and the hanging column and pressure chamber portions of the moisture retention testing by remolding the material into testing rings to target 82% and 88% of the maximum dry bulk density, based on the client provided standard proctor compaction testing results. The density (in pcf) and the percent of maximum dry bulk density achieved were added to the sample ID's. Remaining bulk material was used to prepare sub-samples for the dewpoint potentiometer and relative humidity chamber portions of the moisture retention testing.

Total porosity calculations were performed using an assumed specific gravity value of 2.70.

\(^1\)Target Remold Parameters: Provided by the client.

\(^2\)Volume Change Post Saturation: Volume change measurements were obtained after saturated hydraulic conductivity testing.

\(^3\)Volume Change Post Drying Curve: Volume change measurements were obtained throughout hanging column and pressure chamber testing. The 'Volume Change Post Drying Curve' values represent the final sample dimensions after the last hanging column or pressure chamber measurement.

Notes:

"+" indicates sample swelling, "-" indicates sample settling, and "---" indicates no volume change occurred.
