Solubility in Water of Normal C\textsubscript{9} and C\textsubscript{10}, Alkane Hydrocarbons

Clayton McAuliffe

ABSTRACT

A new method for equilibrating water containing alkane hydrocarbons with a gas phase and analyzing the gas for hydrocarbon content by gas chromatography extends analytical sensitivity to better than 0.1 part per billion. The solubilities at 25°C of the normal C\textsubscript{9} (22 parts per billion) and C\textsubscript{10} (62 parts per billion) alkanes decrease with increasing carbon number. A discontinuity occurs at the normal C\textsubscript{10} alkanes, probably because of a change from true solubility (molecular dispersion) to accommodation (aggregation).
