Re: Transmittal White Mesa Uranium Mill Reclamation Plan, Revision 5.1B

Dear Mr. Anderson:

Attached please find two hard copies and the associated electronic copies of the Energy Fuels Resources (USA) Inc. ("EFRI") White Mesa Mill (the "Mill") Reclamation Plan, Revision 5.1B. Hard copies of the redline and clean versions of the modified sections are included for your convenience. Electronic copies of the redline versions of the modified sections and the clean version of the entire Reclamation Plan are provided.

EFRI prepared this Revision 5.1B to address select public comments on the Mill's Groundwater Discharge Permit and Radioactive Materials License. EFRI responses to public comments were documented in the EFRI letter dated October 23, 2017 and an updated Section 6 of the Main Text to Revision 5.1 of the Plan was provided as an attachment to the October 23, 2017 letter. Reclamation Plan 5.1B, Attachment A (Technical Specifications) and the remaining Main Text sections have also been updated with minor revisions to address public comments and for consistency. The remaining attachments and appendices do not require revisions and therefore the designation of Revision 5.1 or reference to Revision 5.1 remain to indicate changes have not been made to these components of the Plan.

If you should have any questions regarding this transmittal please contact me at 303-389-4134.

Yours very truly,

ENERGY FUELS RESOURCES (USA) INC.

Re: Transmittal White Mesa Uranium Mill Reclamation Plan, Revision 5.1

Dear Mr. Anderson:

Pursuant to discussions with the Division for Waste Management and Radiation Control ("DWMRC") regarding the draft Stipulation and Consent Agreement ("SCA", dated July 1, 2016) for the Cell 2 cover placement activities, Energy Fuels Resources (USA) Inc. ("EFRI") provided the DWMRC with the White Mesa Uranium Mill Reclamation Plan, Revision 5.1 ("Reclamation Plan") on August 10, 2016. DWMRC provided written review comments to EFRI on both documents, including draft redlines on the SCA on September 28, 2016. EFRI revised the SCA and select sections of the Reclamation Plan to address DWMRC's review comments and also incorporate comments resulting from discussions with the DWMRC during a meeting on October 5, 2016 and during follow up conference calls. Select sections of the Reclamation Plan and SCA were submitted on November 11, 2016 to incorporate the above referenced comments. DWMRC provided verbal comments to the November 11, 2016 revisions in a conference call on November 16, 2016. The attached redlines address the verbal comments provided by DWMRC in the November 16, 2016 conference call. This letter transmits the revised documents and includes:

- Two CDs each containing:
  - An electronic file of the revised draft SCA (with redlines since last draft provided to DWMRC)
  - a word searchable electronic copy of the White Mesa Uranium Mill Reclamation Plan, Revision 5.1 dated December 2016 (includes revised sections of the Reclamation Plan since the August 2016 version)
  - electronic file copies of redlined report sections changed since the November 11, 2016 submittal of the Reclamation Plan
- Two sets of hard copies of the revised draft SCA
- Two sets of hard copies of replacement sections to the August 2016 version of the Reclamation Plan. Hard copies include:
  - Binder covers

- o Reclamation Plan main text
- o Drawings
- o Updated Cover Design Report main text (Appendix A to Reclamation Plan)
- o Appendix G to Updated Cover Design Report (main text only)
- o Appendix L to Updated Cover Design Report (main text only)

If you should have any questions regarding this transmittal please contact me at 303-389-4160 or Kathy Weinel at 303-389-4134.

INTRODUCTION

This Reclamation Plan (the "Plan") has been prepared by Energy Fuels Resources (USA) Inc. ("EFRI")[1] for EFRI's White Mesa Uranium Mill (the "Mill"), located approximately six miles south of Blanding, Utah. This Plan presents EFRI's plans and estimated costs for the reclamation of cells for the tailings management system, and for decommissioning of the Mill and Mill site.[2] This Plan is an update to the White Mesa Mill Reclamation Plan Revision 3.2b (Denison, 2011b) approved by the Utah Department of Environmental Quality (UDEQ) Division of Radiation Control (DRC) on January 26, 2011.

Summary of Plan

The uranium and vanadium processing areas of the Mill, including equipment, structures and support facilities, will be decommissioned and disposed of in tailings or buried at the Mill site as appropriate. Equipment (including tankage and piping, agitation, process control instrumentation and switchgears, and contaminated structures) will be cut up, removed, and buried in tailings prior to final cover placement. Concrete structures and foundations will be demolished and removed for disposal in tailings or covered in place with soil as appropriate.

The sequence of demolition will proceed so as to allow the maximum use of support areas of the facility, such as the office and shop areas. Uncontaminated or decontaminated equipment to be considered for salvage will be released in accordance with United States Nuclear Regulatory Commission ("NRC") guidance and in compliance with the conditions of the EFRI's State of Utah Radioactive Materials License No. UT1900479 (the "License"). As with the equipment for disposal, contaminated soils from the Mill and surrounding areas and ore or feed materials on the Mill site will be disposed of in the tailings cells in accordance with Attachment A, Technical Specifications. An evapotranspiration cover system is proposed for reclamation of the tailings management system cells.

The estimated reclamation costs for surety are set out in Attachment C. Attachment C will be reviewed and updated in accordance with License requirements. The reclamation costs are based on the approved Reclamation Plan (Denison, 2011b) and incorporate reclamation work completed to date. The reclamation costs will be updated when this Plan is approved and the Cell 2 cover performance test sections (see Sections 3.0, 5.0, and 6.0) are verified based on requirements outlined in a Stipulation and Consent Agreement (SCA) being developed between EFRI and UDEQ Division of Waste Management and Radiation Control (DWMRC) (see Sections 5.0 and 6.0).

Plan Organization

General site characteristics pertinent to this Plan are contained in Section 1.0. Descriptions of the facility construction, operations and monitoring are given in Section 2.0. The reclamation plan itself, including descriptions of facilities to be reclaimed and design criteria, is presented in Section 3.0. Section 4.0 provides an overview of the preliminary mill decommissioning plan. Section 5.0 presents how reclamation would proceed if the "Proposed Cover Design" in Appendix A is not approved. Milestones and schedule commitments for reclamation are outlined in Section 6.0. Design drawings ("Drawings") are attached to this plan following the main text. Attachments A through D comprise the Technical Specifications,

[1] Prior July 25, 2012 EFRI was "Denison Mines (USA) Corp." and prior to December 16, 2006, Denison was named "International Uranium (USA) Corporation."
[2] Cell 1 was previously referred to as Cell 1-I. It is now referred to as Cell 1.

Construction Quality Assurance/Quality Control (QA/QC) Plan, Reclamation Cost Estimate, and Radiation Protection Manual for Reclamation Activities. Attachment E provides documents on the approved "Existing Cover Design" including the Titan Environmental 1996 Tailings Cover Design Report (Attachment E.1) and Technical Specifications (Attachment E.2). Both documents were included in the approved Reclamation Plan Revision 3.2b (Denison, 2011b).

Supporting documents include:

- *Updated Tailings Cover Design Report,* December 2016. MWH, Inc. (Appendix A)
- *Preliminary Mill Decommissioning Plan,* August 2016. MWH, Inc. (Appendix B)

As required by Part I.H.11 of previous revisions of the Mill's State of Utah Ground Water Discharge Permit No. UGW370004 (the "GWDP"), and Part I.H.2 of the current revision of the GWDP, EFRI completed an infiltration and contaminant transport model of the final tailings cover system to demonstrate the long-term ability of the cover to protect nearby groundwater quality (MWH, 2010). The model was updated to address DWMRC comments on the ICTM Report (DRC, 2012; 2013) and to incorporate additional geotechnical and hydrologic data collected as part of field investigations conducted in 2010 and 2012 for cover borrow material and in 2013 for in situ tailings. The updated infiltration modeling results were presented in EFRI (2012b) and EFRI (2015c). The updated cover design is included in the Updated Tailings Cover Design Report, included as Appendix A to this Reclamation Plan, and includes a monolithic evapotranspiration (ET) cover for the tailings cells. The revised cover design and basis was used for this version of the Plan.

The Reclamation Plan is written assuming Cells 2, 3, 4A, and 4B of the tailings management system will receive tailings to the maximum permitted tailings elevations. Cell 2 is full and partially reclaimed. Cell 3 was used for tailings storage, but currently only receives mill waste and byproduct material in accordance with License provisions. Cell 3 is partially full, and partially reclaimed. Cell 4A is the only cell currently receiving tailings and is partially full. Cell 4B is used for evaporation of process solutions and has not been used for tailings disposal. The Plan has been written assuming Cell 4B will be used in the future for permanent tailings disposal. If Cell 4B is not used in the future for tailings disposal, Cell 4B can be reclaimed for clean closure. This design is not presented in this report.

A Cell 1 Disposal Area is included in the reclamation design to provide additional storage for permanent disposal of contaminated materials and debris from the Mill site decommissioning and windblown cleanup. The current design is approved per the existing License, however this additional storage area is not currently needed for reclamation. If the Cell 1 Disposal Area is required for storage at the time of final Mill decommissioning, the liner system design will be updated to be the same basic design as the liner system for Cell 4B, including the same basic leak detection system. The revised design would be submitted to the Director prior to construction. After approval of the design by the Director, the Plan and surety would be updated to reflect the approved design.

Revisions to this Reclamation Plan include information related to the updated tailings cover design, as well as results of data collection and monitoring since Revision 5.0 of this Plan (Denison, 2011c). Revisions to the attachments and appendices of the Reclamation Plan are listed in a tabular format in Table I-1.

Table I-1
Revisions to Attachments and Appendices in Reclamation Plan

Attachments/ Appendices	Reclamation Plan Revision 5.0 (2011)	Reclamation Plan Revision 5.1B (2018)*
Drawings	Included in Attachment A	**Updated and provided as a standalone attachment**
Attachment A	Plans and Technical Specifications for Reclamation of White Mesa Mill Facility, Blanding, Utah	**Updated -** Technical Specifications for Reclamation of White Mesa Mill Facility, Blanding, Utah
Attachment B	Construction Quality Assurance/Quality Control Plan for Reclamation of White Mesa Mill Facility, Blanding, Utah	**Updated** - Construction Quality Assurance/Quality Control Plan for Reclamation of White Mesa Mill Facility, Blanding, Utah
Attachment C	Cost Estimates for Reclamation of White Mesa Facility in Blanding, Utah	**Updated** - Cost Estimates for Reclamation of White Mesa Facility in Blanding, Utah
Attachment D	Radiation Protection Manual for Reclamation	**Updated -** Radiation Protection Manual for Reclamation Activities
Attachment E	Not included	**Added** – Existing Cover Design Documents
Appendix A	*Semi-Annual Effluent Report* (January through June, 2011), for the Mill	**Deleted to reduce redundancy** (latest report was submitted to DWMRC)
Appendix B	*Hydrogeology of the Perched Groundwater Zone and Associated Seeps and Springs Near the White Mesa Uranium Mill Site, Blanding, Utah*, November 12, 2010, prepared by Hydro Geo Chem, Inc. (the "2010 HGC Report")	**Deleted to reduce redundancy** (latest report was submitted to DWMRC)
Appendix C	The Mill's *Stormwater Best Management Practices Plan*, Revision 1.3, June 12, 2008, *Emergency Response Plan*, Revision 2.1, August 18, 2009, and Spill Prevention, Control, and Countermeasures Plan, 2011.	**Deleted to reduce redundancy** (latest report was submitted to DWMRC)
Appendix D	*Updated Tailings Cover Design Report*, White Mesa Mill, September 2011. MWH Americas, Inc.	**Updated and now Appendix A -** *Updated Tailings Cover Design Report*, White Mesa Mill, December 2016. MWH, Inc.
Appendix E	*National Emission Standards for Hazardous Air Pollutants Radon Flux Measurement Program, White Mesa Mill Site*, 2010, Tellco Environmental	**Deleted to reduce redundancy** (latest report was submitted to DWMRC)
Appendix F	*Semi-Annual Monitoring Report January 1 - June 30, 2010, White Mesa Mill Meteorological Station*, August 19, 2011, McVehil-Monnett Associates, Inc.	**Deleted to reduce redundancy** (latest report was submitted to DWMRC).
Appendix G	*Preliminary Mill Decommissioning Plan*, White Mesa Mill, September 2011, MWH Americas, Inc.	**Updated and now Appendix B** - *Preliminary Mill Decommissioning Plan*, White Mesa Mill, August 2016, MWH, Inc.

*Main Text and Attachment A were updated from Revision 5.1 to 5.1B (see Section 1).

1 SITE CHARACTERISTICS

EFRI operates the Mill, which is located approximately six miles south of Blanding, Utah (see Figures 1-1 and 1-2). The Mill was initially licensed by the NRC in May 1980 under NRC Source Material License No. SUA-1358. Upon the State of Utah becoming an Agreement State for uranium mills in August 2004, the Mill's NRC license was replaced with the Mill's current State of Utah License and the Mill's GWDP.

The License was up for timely renewal on March 31, 2007 in accordance with Utah Administrative Code ("UAC") R313-22-36.[3] In accordance with R313-22-36, EFRI submitted an application to the Director ("Director") of Utah Department of Environmental Quality, Division of Waste Management and Radiation Control ("DWMRC")[4] on February 27, 2007 for renewal of the License under R313-22-37 (the "2007 License Renewal Application"). Similarly, the GWDP was up for timely renewal on March 8, 2010, in accordance with UAC R317-6-6.7. In 2009, 2012, and 2014, EFRI filed an application to the DWMRC for renewal of the GWDP for under R313-6-6.7.

The Mill is also subject to State of Utah Air Quality Approval Order DAQE-AN1205005-06 (the "Air Approval Order") which was re-issued on March 2, 2011 and is not up for renewal at this time.

Revision 3.0 of this Plan was submitted to and approved by NRC in 2000. A copy of Revision 3.0 of this Plan was also submitted to the DWMRC as part of the 2007 License Renewal Application. The most recently approved version of the Reclamation Plan is Revision 3.2b (Denison, 2011a). This version of the Reclamation Plan was approved by DRC under the Mill License on January 26, 2011. A copy of the White Mesa Mill Reclamation Plan, Revision 4.0 was previously submitted to the Director in November 2009 and is on file at the DRC. This version and previous versions of the Reclamation Plan presented design criteria for a multi-layered cover system. Revision 5.0 of this Plan was submitted to the DWMRC in September 2011. EFRI prepared Revision 5.0 of the Plan to incorporate changes since 2009 and to address interrogatories from the DWMRC (DRC, 2010 and 2011). EFRI prepared Revision 5.1 of the Plan to incorporate changes since 2011 and include updates provided in EFRI response to interrogatories and review comments from DWMRC on Reclamation Plan, Revision 5.0 (Denison, 2012; EFRI, 2012a; EFRI, 2015). EFRI prepared this Revision 5.1B to address select public comments on the White Mesa Mill Groundwater Discharge Permit and Radioactive Materials License. EFRI responses to public comments were documented in EFRI (2017) and an updated Section 6 to Revision 5.1 of the Plan was provided as an attachment. Attachment A (Technical Specifications) has also been updated for Revision 5.1B with a minor revision to address public comments. The remaining attachments and appendices do not require revisions and therefore the designation of Revision 5.1 or reference to Revision 5.1 remain to indicate changes have not been made to these components of the Plan.

This Section 1.0 of the Plan incorporates by reference, updates or supplements, information previously submitted in previous environmental analyses performed at the Mill, as described below.

[3] The License was originally issued by the NRC as a source material license under 10 CFR Part 40 on March 31, 1980. It was renewed by NRC in 1987 and again in 1997. After the State of Utah became an Agreement State for uranium mills in August 2004, the License was re-issued by the DWMRC as a State of Utah Radioactive Materials License on February 16, 2005, but the remaining term of the License did not change.

[4] Prior to 2015, the DWMRC was two separate divisions of UDEQ, the Division of Radiation Control and the Division of Solid and Hazardous Waste.

A Final Environmental Statement Related to Operation of White Mesa Uranium Project, Energy Fuels Nuclear, Inc., May, 1979, Docket No. 40-8681 (the "FES") was prepared by NRC for the original License application in May 1979, which is incorporated by reference into, updated or supplemented by this Section 1.0. The basis for the FES was the *Environmental Report, White Mesa Uranium Project San Juan County, Utah*, dated January 1978, prepared by Dames & Moore (the "1978 ER"). In addition, the following environmental evaluations and other reports have been performed for the Mill and are incorporated by reference into, updated or supplemented by this Section 1.0:

- the Environmental Assessment ("EA") prepared for this Plan in February 2000 by NRC (the "2000 EA");
- the EA prepared in August 2002 by NRC (the "2002 EA") in connection with a License amendment issued by NRC authorizing receipt and processing at the Mill of certain alternate feed materials from the Maywood Formerly Utilized Sites Remedial Action Program site in Maywood, New Jersey;
- the *Statements of Basis* prepared in December 2004 by the State of Utah Department of Environmental Quality ("UDEQ") DWMRC in connection with the issuance of the GWDP revisions (the "GWDP Statement of Basis");
- the *Environmental Report in Support of the License Renewal Application, State of Utah Radioactive Materials License No. UT1900479*, prepared by Denison Mines (USA), Inc., February 28, 2007 (the "2007 ER");
- Background Groundwater Quality Reports, Source Assessment Reports (SARs), Pyrite Investigation Report and pH Report as discussed in Section 1.5.4.

1.1 Climate and Meteorology

1.1.1 Regional

The climate of southeastern Utah is classified as dry to arid continental. Although varying somewhat with elevation and terrain, the climate in the vicinity of the Mill is semi-arid with normal annual precipitation of about 13.32 inches (see Table 1.1-1). Most precipitation is in the form of rain with snowfall accounting for about 29 percent of the annual total precipitation. There are two separate rainfall seasons in the region, the first in late summer and early autumn (August to October) and the second during the winter months (December to March). The mean annual relative humidity is about 44 percent and is normally highest in January and lowest in July. The average annual Class A pan evaporation rate is 68 inches (NOAA, 1977), with the largest evaporation rate typically occurring in July. This evaporation rate is not appropriate for determining water balance requirements for the tailings management system and must be reduced by the Class A pan coefficient to determine the latter evaporation rate. Values of pan coefficients range from 60 to 81 percent. EFRI assumes for water balance calculations an average value of 70 percent to obtain an annual lake evaporation rate for the Mill area of 47.6 inches. Given the annual average precipitation rate of 13.32 inches, the net evaporation rate is 34.28 inches per year.

The weather in the Blanding area is typified by warm summers and cold winters. The National Weather Service Station in Blanding, Utah is located about 6.25 miles north of the Mill. Data from the station is considered representative of the local weather conditions (1978 ER, Section 2.7.2). The mean annual temperature in Blanding was 50.3°F, based on the Period of Record Summary (1904 - 2006). January is usually the coldest month and July is usually the warmest month (see Table 1.1-2).

Table updated on Jul 28, 2006
For monthly and annual means, thresholds, and sums:
Months with 5 or more missing days are not considered
Years with 1 or more missing months are not considered
Seasons are climatological not calendar seasons

Winter = Dec., Jan., and Feb. Spring = Mar., Apr., and May
Summer = Jun., Jul., and Aug. Fall = Sep., Oct., and Nov.

Winds are usually light to moderate in the area, although occasional stronger winds may occur in the late winter and spring. The predominant winds are from the north through north-east (approximately 30 percent of the time) and from the south through south-west (about 25 percent of the time). Winds are generally less than 15 mph, with wind speeds greater than 25 mph occurring less than one percent of the time (1978 ER, Section 2.7.2). As an element of the pre-construction baseline study and ongoing monitoring programs, the Mill operates an onsite meteorological station, described below. Further details about weather and climate conditions are provided in the 1978 ER (Section 2.7) and in the FES (Section 2.1).

1.1.2 Storms (FES Section 2.1.4, updated)

Thunderstorms are frequent during the summer and early fall when moist air moves into the area from the Gulf of Mexico. Related precipitation is usually light, but a heavy local storm can produce over an inch of rain in one day. The maximum 24-hour precipitation reported to have fallen during period 1904-2006 at Blanding was 4.48 inches (11.36 cm). Hailstorms are uncommon in this area. Although winter storms may occasionally deposit comparable amounts of moisture, maximum short-term precipitation is usually associated with summer thunderstorms.

Tornadoes have been observed in the general region, but they occur infrequently. Strong winds can occur in the area along with thunderstorm activity in the spring and summer. The Mill area is susceptible to occasional dust storms, which vary greatly in intensity, duration, and time of occurrence. The basic conditions for blowing dust in the region are created by wide areas of exposed dry topsoil and strong, turbulent winds. Dust storms usually occur following frontal passages during the warmer months and are occasionally associated with thunderstorm activities.

1.1.3 On Site

On-site meteorological monitoring at the Mill was initiated in early 1977 and continues today. The original purpose of the meteorological monitoring program was to document the regional atmospheric baseline and to provide data to assist in assessing potential air quality and radiological impacts arising from operation of the Mill.

After the Mill construction was completed, the monitoring programs were modified to facilitate the assessment of Mill operations. The current meteorological monitoring program includes data collection for wind speed, wind direction, atmospheric stability according to the standard Pasquill scheme (via measurements of deviations in wind direction, referred to as sigma-theta), and precipitation as either rain or snow. The recorded on-site meteorological conditions are reported to EFRI on a semi-annual basis and are described in semi-annual reports maintained at the Mill. Figure 1.1-1 shows the windrose for the Mill site for January – December 2015, the most recent full year of compiled meteorological data.

1.2 Topography

The following text is reproduced from Section 2.3 of the FES.

The site is located on a "peninsula" platform tilted slightly to the south-southeast and surrounded on almost all sides by deep canyons, washes, or river valleys. Only a narrow neck of land connects this platform with high country to the north, forming the foothills of the Abajo Mountains. Even along this neck, relatively deep stream courses intercept overland flow from the higher country. Consequently, this platform (White Mesa) is well protected from runoff flooding, except for that caused by incidental rainfall directly on the mesa itself. The land on the mesa immediately surrounding the Mill site is relatively flat.

1.3 Archeological Resources

The following discussion of archeological sites is adapted from Section 2.5.2.3 of the FES.

1.3.1 Archeological Sites

Archeological surveys of portions of the entire Mill site were conducted between the fall of 1977 and the spring of 1979. The total area surveyed contained parts of Section 21, 22, 27, 28, 32, and 33 of T37S, R22E, and encompassed 2,000 acres (809 ha), of which 200 acres (81 ha) are administered by the U. S. Bureau of Land Management (“BLM”) and 320 acres (130 ha) are owned by the State of Utah. The remaining acreage is privately owned. During the surveys, 121 archeological sites were recorded and all were determined to have an affiliation with the San Juan Anasazi who occupied this area of Utah from 0 A.D. to 1300 A.D. All but 22 of the sites were within the Mill site boundaries.

Table 1.3-1, adapted from FES Table 2.18, summarizes the recorded sites according to their probable temporal positions. The dates of occupation are the best estimates available, based on professional experience and expertise in the interpretation of archeological evidence. Available evidence suggests that settlement on White Mesa reached a peak in perhaps 800 A.D. Occupation remained at approximately that level until sometime near the end of Pueblo II or in the Pueblo II/Pueblo III transition period. After this period, the population density declined sharply, and it may be assumed that the White Mesa area was, for the most part, abandoned by about 1250 A.D.

Archeological test excavations were conducted by the Antiquities Section, Division of State History, in the spring of 1978, on 20 sites located in the area later to be occupied by Cells 2, 3 and 4 (now comprised of Cell 4A and Cell 4B). Of these sites, 12 were deemed by the State Archeologist to have significant National Register potential and four to have possible significance. The primary determinant of significance in this study was the presence of structures, though storage features and pottery artifacts were also common.

In the fall of 1978, a surface survey was conducted on much of the previously unsurveyed portions of the proposed Mill site. Approximately 45 archeological sites were located during this survey, some of which are believed to be of equal or greater significance than any sites from the earlier study. Determination of the actual significance of all untested sites would require additional field investigation.

Table 1.3-1
Distribution of Recorded Sites According to Temporal Position

Temporal position	Approximate dates (A.D.)*a*	Number of sites
Basket Maker III	575-750	2
Basket Maker III/Pueblo I	575-850	27
Pueblo I	750-850	12
Pueblo I/Pueblo II	850-950	13
Pueblo II	950-1100	14
Pueblo II/Pueblo III	1100-1150	12
Pueblo III	1150-1250	8
Pueblo II+	*B*	
Multicomponent	*C*	3
Unidentified	*D*	14

a Includes transitional periods.
b Although collections at these locations were lacking in diagnostic material, available evidence indicates that the site would have been used or occupied no earlier than 900 A.D. and possibly later.
c Ceramic collections from each of these sites indicate an occupation extending from Pueblo I through Pueblo II and into Pueblo III.
d These sites did not produce evidence strong enough to justify any identification.

Source: Adapted from Dames & Moore (1978b) (1978 ER), Table 2.3-2, FES, Page 2-20, Table 2.18, and from supplementary reports on project archeology.

Pursuant to 10 CFR Part 63.3, the NRC submitted on March 28, 1979, a request to the Keeper of the National Register for a determination of eligibility for the area which had been surveyed and tested. The area contained 112 archeological sites and six historical sites. The determination by the Keeper of the National Register on April 6, 1979, was that the White Mesa Archeological District is eligible for inclusion in the National Register.

1.3.2 Current Status of Excavation

Archeological investigations for the entire Mill site and for Cells 1 through Cell 4 (now comprised of Cell 4A and Cell 4B) were completed with the issuance of four separate reports covering 30 sites, excluding re-investigations. (Lindsay 1978, Nielson 1979, Casjens et al 1980, and Agenbroad et al 1981).

The sites reported as excavated are as follows:

6380	6394	6437
6381	6395	6684
6384	6396	6685
6385	6397	6686
6386	6403	6697
6387	6404	6698
6388	6420	6699
6391	6429	6754
6392	6435	6757
6393	6436	7754

Sites for which excavation has not been required are:

6379	6441	7658	7690
6382	6443	7659	7691
6405	6444	7660	7693

The sites remaining to be excavated or investigated for significance are:

6408	6445	7657	7687
6421	6739	7661	7689
6427	6740	7665	7696
6430	7653	7668	7700
6432	7655	7675	7752
6439	7656	7684	7876

The following site was excavated in 2009 in connection with the construction of the new decontamination pad at the Mill:

42Sa27732

The following sites were excavated in the summer of 2010 in connection with the construction of Cell 4B and a final report was prepared:

42Sa6391	42Sa6431	42Sa28129	42Sa28133
42Sa6392	42Sa6757	42Sa28130	42Sa28134
42Sa6393	42Sa8014	42Sa28131	
42Sa6397	42Sa28128	42Sa28132	

1.4 Surface Water

The following description of undisturbed surface water conditions is adapted from Section 2.6.1 of the FES and Section 3.7.1 of the 2007 ER and is updated to include current data.

The Mill was designed and constructed to prevent run-on or runoff of stormwater by a) diverting runoff from precipitation on the Mill site to the tailings management cells; and b) diverting runoff from surrounding areas away from the Mill site. In addition to these designed control features, the facility has developed a *Stormwater Best Management Practices Plan*, Revision 1.5: May 2, 2016 (EFRI, 2016) which describes site drainage features and the best management practices employed to assure appropriate control and routing of stormwater.

1.4.1 Surface Water Description (FES Section 2.6.1.1)

The Mill site is located on White Mesa, a gently sloping (1 percent SSW) plateau that is physically defined by the adjacent drainages which have cut deeply into regional sandstone formations. There is a small drainage area of approximately 62 acres (25 ha) above the site that could yield surface runoff to the site. Runoff from the Mill area is conducted by the general surface topography to either Westwater Creek, Corral

Creek, or to the south into an unnamed branch of Cottonwood Wash. Local porous soil conditions, topography and low acreage annual rainfall of 13.32 inches cause these streams to be intermittently active, responding to spring snowmelt and local rainstorms (particularly thunderstorms). Surface runoff from approximately 384 acres (155 ha) of the Mill site drains westward and is collected by Westwater Creek, and runoff from another 384 acres (155 ha) drains east into Corral Creek. The remaining southern and southwestern portions of the site drain indirectly into Cottonwood Wash (Dames & Moore, 1978b, p. 2-143). The site and vicinity drainages carry water only on an intermittent basis. The major drainages in the project vicinity are depicted on Figure 1.4-1 and their drainages tabulated in Table 1.4-1. Total runoff from the site area (total yield per watershed area) is estimated to be less than 0.5 inch (1.3 cm) annually (Dames & Moore, 1978b, p. 2-143).

There are no perennial surface waters on or in the vicinity of the Mill site. This is due to the gentle slope of the mesa on which the site is located, the low average annual rainfall of 13.32 inches (33.8 cm) per year at Blanding, local soil characteristics and the porous nature of local stream channels. Prior to construction, three small ephemeral catch basins were present on the site to the northwest and northeast of the Mill site.

Corral Creek is an intermittent tributary to Recapture Creek. The drainage area of that portion of Corral Creek above and including drainage from the eastern portion of the site is about 5 square miles (13 km^2). Westwater Creek is also an intermittent tributary of Cottonwood Wash. The Westwater Creek drainage basin covers nearly 27 square miles (70 km^2) at its confluence with Cottonwood Wash 1.5 miles (2.5 km) west of the Mill site. Both Recapture Creek and Cottonwood Wash are similarly intermittently active, although they carry water more often and for longer periods due to their larger watershed areas. They both drain to the south and are tributaries of the San Juan River. The confluences of Recapture Creek and Cottonwood Wash with the San Juan River are approximately 18 miles (29 km) south of the Mill site. The San Juan River, a major tributary for the upper Colorado River, has a drainage of 23,000 square miles (60,000 km^2) measured at the USGS gauge to the west of Bluff, Utah (Dames & Moore, 1978b, p. 2-130).

Source: Adapted from Dames & Moore (1978b), Table 2.6-3

Storm runoff in these streams is characterized by a rapid rise in the flow rates, followed by rapid recession primarily due to the small storage capacity of the surface soils in the area. For example, on August 1, 1968, a flow of 20,500 cfs (581 m^3/sec) was recorded in Cottonwood Wash near Blanding. The average flow for that day, however, was only 4,340 cfs (123 m^3/sec). By August 4, the flow had returned to 16 cfs (0.5 m^3/sec) (Dames & Moore, 1978b, p. 2-135). Monthly streamflow summaries updated from Figure 2.4 of the FES are presented in Figure 1.4-2 for Cottonwood Wash, Recapture Creek and Spring Creek. Flow data are not available for the two smaller water courses closest to the Mill site, Corral Creek and Westwater Creek, because these streams carry water infrequently and only in response to local heavy rainfall and snowmelt, which occurs primarily in April, August, and October. Flow typically ceases in Corral and Westwater Creeks within 6 to 48 hours after precipitation or snowmelt ends.

1.4.2 Surface Water Quality as of the Date of the FES (FES Section 2.6.1.2)

Sampling of surface water quality in the Mill vicinity began in July 1977 and continued through March 1978. Baseline data describe and evaluate existing conditions at the Mill site and vicinity. Sampling of the temporary on-site surface waters (two catch basins) was attempted, but without success because of the lack of naturally occurring water in these basins. Sampling of ephemeral surface waters in the vicinity was possible only during major precipitation events, as these streams are normally dry. See FES Section 2.6.1.2.

Surface water sample sites used prior to Mill operations are presented on Figure 1.4-3. The water quality values obtained for these sample sites are given in Dames & Moore (1978b) Table 2.6-7, and FES Table 2.22. Water quality samples were collected during the spring at several intermittently active streams that drain the Mill area. These streams include Westwater Creek (S1R, S9) Corral Creek below the small irrigation pond (S3R), the junction of Corral Creek and Recapture Creek (S4R), and Cottonwood Creek (S8R). Samples were also taken from a surface pond southeast of the Mill (S5R). No samples were taken at S2R on Corral Creek or at the small wash (S6R) located south of the site.

W:\USA\Utah\Mill\dwgs\Reclamation Plans\Rev_07-2011\Work01_Harold\Fig.1.4-3_SurfaceWaterSampling.dwg Layout1 GMoseley

Natural surface water quality in the vicinity of the Mill is generally poor. Waters in Westwater Creek (S1R and S9) were characterized by high total dissolved solids (TDS; mean of 674 mg/liter) and sulfate levels (mean 117 mg of SO_4 per liter). The waters were typically hard (total hardness measured as $CaCO_3$; mean 223 mg/liter) and had an average pH of 8.25. Estimated water velocities for Westwater Creek averaged 0.3 fps (0.08 m/sec) at the time of sampling.

Samples from Cottonwood Creek (S8R) at the time of the FES were generally similar in quality to Westwater Creek water samples, although the TDS and sulfate levels were lower (TDS averaged 264 mg/liter; SO_4 averaged 40 mg/liter) during heavy spring flow conditions (80 fps [24 m/sec] water velocity).

The concentrations of TDS increased downstream in Corral Creek, averaging 3,180 mg/liter at S3R and 6,660 mg/liter (one sample) at S4R. Total hardness averaged in excess of 2,000 mg/liter, and pH values were slightly alkaline. Estimated water velocities in Corral Creek were typically less than 0.1 fps (0.03 m/sec) during sampling.

The spring sample collected at the surface pond south of the Mill site (S5R) indicated a TDS concentration of less than 300 mg/liter. The water was slightly alkaline with moderate dissolved sulfate levels averaging 42 mg/liter.

During heavy runoff, the concentration of total suspended solids in these streams increased sharply to values in excess of 1,500 mg/liter (FES, Table 2.22). High concentrations of certain trace elements were measured in some sampling areas. Levels of mercury (total) were reported as high as 0.002 mg/liter (S3R, 7/25/77; S8R, 7/25/77). Total iron measured in the pond (S5R, 11/10/77) was 9.4 mg/liter. The FES concluded (Section 2.6.1.2 of the FES) that these values appear to reflect groundwater quality in the vicinity and are probably due to evaporative concentration and not due to human perturbation of the environment. Corral Creek was also sampled at the time of the FES, but it has not been included in subsequent operational monitoring at the Mill. See Table 2.22 of the FES for sampling results for Corral Creek.

1.4.3 Surface Water Background Quality

Surface water samples are collected for Cottonwood Wash and Westwater Creek as part of the Mill's operational monitoring program. Samples were also taken prior to Mill construction and summarized in the FES as well as at various times and for various parameters since then. A comparison of the FES results and subsequent sampling results during Mill operation is shown in Table 1.4-2. Surface water values over time for both Cottonwood Wash and Westwater Creek are included in the Semi-Annual Effluent Reports.

1.5 Groundwater

Groundwater investigation and monitoring at the Mill focus on the perched groundwater zone, which is the shallowest groundwater encountered beneath the site. Although this section focuses primarily on the perched water zone, deeper groundwater is discussed as needed, and the site geology is addressed to the extent necessary for interpretive context. A more extensive discussion of site geology is provided in Section 1.6.

Sections 1.5.1 and 1.5.2 are based primarily on the following reports prepared by Hydro Geo Chem, Inc. ("HGC"): *Hydrogeology of the Perched Groundwater Zone and Associated Seeps and Springs Near the White Mesa Uranium Mill Site* (HGC, 2010b), and *Hydrogeology of the White Mesa Uranium Mill, Blanding, Utah* (HGC, 2014). Information abstracted from these reports presented here is updated with information collected subsequent to June 6, 2014.

HGC (2010b) and HGC (2014) supplement the "HGC 2009" report summarized in Revision 4.0 of the Reclamation Plan. They provide additional information in response to requirements set out in previous revisions of the GWDP and Part 1F.10 of the current GWDP dated August 24, 2012. Specifically, the additional information contained in HGC (2010b) and HGC (2014) include data on seeps and springs in the vicinity of the Mill, the relationship of the seeps and springs with the perched water system, and estimated travel times for shallow groundwater to travel from the tailings cells to the nearest discharge points. This information addresses requirements set out in previous revisions of the GWDP and Part 1F.10 of the current GWDP dated August 24, 2012. HGC (2014) contains refined estimates of shallow groundwater travel times downgradient of the tailings cells based on data collected from DR-series piezometers installed south, southwest, and west of the tailings cells in 2011, as described in *Second Revision, Hydrogeology of the Perched Groundwater Zone in the Area Southwest of the Tailings Cells, White Mesa Uranium Mill Site, Blanding Utah* (HGC 2012b; the "southwest area investigation" report).

Sections 1.5.3, 1.5.5, and 1.5.6 are based primarily on groundwater sampling programs at the Mill and Section 1.5.4 is based primarily on the analysis of groundwater analytical data by INTERA, Inc. (INTERA). INTERA performed extensive analysis of background perched water quality data and established site-specific groundwater compliance limits ("GWCLs"). Reports detailing work by INTERA include *Revised Background Groundwater Quality Report: Existing Wells For Denison Mines (USA) Corp.'s White Mesa Mill Site, San Juan County, Utah* (INTERA 2007a), and subsequent reports, as discussed in Section 1.5.4.

1.5.1 Groundwater Characteristics

Groundwater investigations at the Mill have been ongoing for more than 38 years, beginning with the initial investigation by Dames and Moore in 1977 and 1978 (Dames and Moore 1978a and 1978b). The initial investigation by Dames and Moore pre-dated Mill construction and operation.

Although more than 35 years of perched groundwater monitoring at the Mill indicates that tailings cell operation has not impacted perched groundwater (as will be discussed in Section 1.5.4), perched groundwater was impacted by disposal of laboratory wastes to two (now abandoned) sanitary leach fields (prior to about 1980) before the Mill and tailings cells were operational. Disposal of laboratory wastes is considered the source of a chloroform plume (defined by concentrations greater than 70 micrograms per liter [µg/L]) located upgradient to cross-gradient (northeast to east) of the tailings cells. A nitrate plume (defined by concentrations greater than 10 milligrams per liter [mg/L]) that contains elevated chloride (exceeding 100 mg/L) extends from upgradient (northeast) of the tailings cells to a portion of the area beneath the tailings cells. The precise source(s) of the nitrate plume are not well defined; however, because the majority of the plume exists upgradient (northeast) of the tailings cells, the sources must be located upgradient (northeast) of the tailings cells. Based on the investigation and source evaluations, there are no known current unidentified or unaddressed sources. There appear to have been a number of known and potential historical sources; however, it has not been possible to confirm or quantify the contribution of each source.

The northwest portion of the chloroform plume commingles with the nitrate plume. Both chloroform and nitrate plumes are under corrective action by pumping.

1.5.1.1 Geologic Setting

The Mill is located within the Blanding Basin of the Colorado Plateau physiographic province. Typical of large portions of the Colorado Plateau province, the rocks underlying the site are relatively undeformed. The average site elevation is approximately 5,600 ft (1,707 m) above mean sea level (amsl).

The site is underlain by unconsolidated alluvium and indurated sedimentary rocks consisting primarily of sandstone and shale. The indurated rocks are relatively flat lying with dips generally less than 3 degrees. The alluvial materials consist mostly of aeolian silts and fine-grained aeolian sands with a thickness varying from a few feet to as much as 25 to 30 ft (7.6 to 9.1 m) across the site. The alluvium is underlain by the Dakota Sandstone and Burro Canyon Formation, which are sandstones with a total thickness ranging from approximately 55 to 140 ft (17 to 43 m). Beneath the Burro Canyon Formation lies the Morrison Formation, consisting (in descending order) of the Brushy Basin Member, the Westwater Canyon Member, the Recapture Member, and the Salt Wash Member. Kirby (2008) indicates that the contact between the Morrison Formation and the Burro Canyon Formation (between the Brushy Basin Member of the Morrison and the Burro Canyon Formation) near Blanding, Utah is disconformable with “local erosional relief of several feet”. Data collected from perched borings at the site that penetrate the Brushy Basin Member are consistent with a disconformable, erosional contact in agreement with Kirby (2008).

The Brushy Basin and Recapture Members of the Morrison Formation, classified as shales, are fine-grained and have a low permeability. The Westwater Canyon and Salt Wash Members also have a low average vertical permeability due to the presence of interbedded shales. See Figure 1.5-1 for a generalized stratigraphic column for the region.

Beneath the Morrison Formation lies the Summerville Formation, an argillaceous sandstone with interbedded shales, and the Entrada Sandstone. Beneath the Entrada Sandstone lies the Navajo Sandstone. The Navajo and Entrada Sandstones constitute the primary aquifer in the area of the site. The Entrada and Navajo Sandstones are separated from the Burro Canyon Formation by approximately 1,000 to 1,100 ft (305 to 335 m) of materials with a low average vertical permeability. Groundwater within this system is under artesian pressure in the vicinity of the site, and is used only as a secondary source of water at the site. Water in WW-series supply wells completed across these sandstone units at the site rises approximately 800 feet above the base of the overlying Summerville Formation (Titan, 1994a).

1.5.1.2 Hydrogeologic Setting

The site is located within a dry to arid continental climate region with an average annual precipitation of less than 13.3 in. and an annual lake evaporation rate of approximately 47.6 inches. Recharge to aquifers (such as the Entrada/Navajo) occurs primarily along the mountain fronts (for example, the Henry, Abajo, and La Sal Mountains), and along the flanks of folds such as Comb Ridge Monocline.

The Entrada/Navajo aquifer can yield significant quantities of water to wells (hundreds of gallons per minute [gpm]). Although the water quality and productivity of the Entrada/Navajo aquifer are generally good, the depth of the aquifer (approximately 1,200 ft below land surface [bls]) makes access difficult.

1.5.1.3 Perched Zone Hydrogeology

Perched groundwater beneath the site occurs primarily within the Burro Canyon Formation, although in areas having greater saturated thicknesses, perched groundwater extends into the overlying Dakota Sandstone. Perched groundwater originates mainly from precipitation and local recharge sources such as unlined reservoirs (Kirby, 2008). Perched groundwater at the site has a generally low quality due to high total dissolved solids (TDS) and is used primarily for stock watering and irrigation in the areas upgradient (north) of the site. As of the first quarter of 2016, TDS concentrations measured in water sampled from on-site perched monitoring wells range between approximately 1,000 and 8,300 mg/1. The saturated thickness of the perched water zone generally increases to the north of the site, increasing the yield of the perched zone to wells installed north of the site. Perched water is supported within the Burro Canyon Formation by the underlying, fine-grained Brushy Basin Member.

The Brushy Basin Member is primarily composed of bentonitic mudstones, siltstones, and claystones and is considered an aquiclude. Figure 1.5-2 is a contour map showing the approximate elevation of the contact of the Burro Canyon Formation with the Brushy Basin Member, which essentially forms the base of the perched water zone at the site. The elevations of Ruin Spring and Westwater Seep, which occur at the contact between the Brushy Basin Member and the Burro Canyon Formation, are included in the contouring. Abandoned borings/wells, monitoring wells, and piezometers shown on Figure 1.5-2 consist of surveyed perched zone monitoring wells and piezometers that include temporary perched zone borings and monitoring wells associated with the chloroform and nitrate plumes located east and northeast (cross gradient to upgradient) of the tailings cells. TW-4-series wells, MW-4, MW-26, and MW-32 are chloroform program wells and TWN-series wells are nitrate program wells. Contact elevations are based on monitoring well drilling and geophysical logs and surveyed land surface elevations.

As indicated on Figure 1.5-2, the contact generally dips to the south/southwest beneath the site. A structural high that is evident in the Brushy Basin Member/Burro Canyon Formation contact extends from beneath Cell 4B southwest to the vicinity of abandoned boring DR-18. A paleovalley in the Brushy Basin Member surface is present along the western mesa rim to the west of the structural high.

The permeability of the Dakota Sandstone and Burro Canyon Formation at the site is generally low. No significant joints or fractures within the Dakota Sandstone or Burro Canyon Formation have been documented in any wells or borings installed across the site (Knight Piésold, 1998). Any fractures observed in cores collected from site borings are typically cemented, showing no open space.

Based on samples collected during installation of wells MW-16 (immediately downgradient of tailings cell 3 and abandoned prior to construction of cell 4B) and MW-17 (cross-gradient of the tailings cells complex (Figure 1.5-2)), porosities of the Dakota Sandstone range from 13.4 percent to 26 percent, averaging 20 percent. Water saturations range from 3.7 percent to 27.2 percent, averaging 13.5 percent. The average volumetric water content is approximately 3 percent. The hydraulic conductivity of the Dakota Sandstone, based on packer tests in borings installed at the site, ranges from 2.71E-06 centimeters per second (cm/s) to 9.12E-04 cm/s, with a geometric average of 3.89E-05 cm/s (Titan, 1994a).

The average porosity of the Burro Canyon Formation is similar to that of the Dakota Sandstone. Based on samples collected from the Burro Canyon Formation at MW-16 (abandoned), porosity ranges from 2 percent to 29.1 percent, averaging 18.3 percent. Water saturations of unsaturated materials range from 0.6 percent to 77.2 percent, averaging 23.4 percent. Titan (1994a) reported that the hydraulic conductivity of the Burro Canyon Formation ranges from 1.9E-07 to 1.6E-03 cm/s, with a geometric mean of 1.1E-05 cm/s, based on the results of 12 pump/recovery tests performed in monitoring wells and 30 packer tests performed in borings prior to 1994.

Subsequent hydraulic testing of perched zone wells yielded a site-wide hydraulic conductivity range of 2 x 10^{-8} to 0.01 cm/s (HGC, 2014). In general, the highest permeabilities and well yields are immediately northeast and east (upgradient to cross gradient) of the tailings cells. A relatively continuous, higher permeability zone (associated with poorly indurated coarser-grained materials in the general area of the chloroform plume) has been inferred to exist in this portion of the site. Analysis of drawdown data collected from this zone during long-term pumping of MW-4, MW-26 (formerly TW4-15), and TW4-19 yielded estimates of hydraulic conductivity ranging from 4E-05 to 1E-03 cm/s. The decrease in perched zone permeability south, southwest, and southeast of TW4-4, based on hydraulic tests at TW4-6, TW4-23, TW4-26, TW4-27, TW4-29 through TW4-31, and TW4-33 through TW4-35 indicate that this higher permeability zone “pinches out”.

Hydraulic tests performed at groups of wells and piezometers located northeast (upgradient) of, in the immediate vicinity of, and southwest (downgradient) of the tailings cells indicate generally lower permeabilities compared with the area of the chloroform plume. The following results from HGC (2014) are based on analysis of automatically logged slug test data using the KGS solution available in AQTESOLVE (HydroSOLVE, 2000).

Testing of 19 TWN-series wells installed in the northeast portion of the site as part of nitrate investigation activities yielded a hydraulic conductivity range of approximately 3.6 x 10^{-7} to 0.01 cm/s with a geometric average of approximately 6 x 10^{-5} cm/s. The value of 0.01 cm/s estimated for TWN-16 is the highest measured at the site, and the value of 3.6 x 10^{-7} cm/s estimated for TWN-7 is one of the lowest measured at the site. Testing of MW-series wells MW-23 through MW-32 installed between and at the margins of the tailings cells in 2005 (and using the higher estimate for MW-23) yielded a hydraulic conductivity range of approximately 2 x 10^{-7} to 1 x 10^{-4} cm/s with a geometric average of approximately 2 x 10^{-5} cm/s. Hydraulic tests conducted at DR-series piezometers installed as part of the southwest area investigation downgradient of the tailings cells yielded hydraulic conductivities ranging from approximately 2 x 10^{-8} to 4 x 10^{-4} cm/s with a geometric average of 9.6 x 10^{-6} cm/s. The low permeabilities and shallow hydraulic gradients downgradient of the tailings cells result in average perched groundwater pore velocity estimates that are among the lowest on site (approximately 0.26 feet per year (ft/yr) to 0.91 ft/yr).

The extensive hydraulic testing of perched zone wells at the site indicates that perched zone permeabilities are generally low with the exception of the apparently isolated zone of higher permeability associated with the chloroform plume east to northeast (cross-gradient to upgradient) of the tailings cells. The geometric average hydraulic conductivity (less than 1 x 10^{-5} cm/s) of the DR-series piezometers which cover an area nearly half the size of the total monitored area at White Mesa (excluding MW-22), is nearly identical to the geometric average hydraulic conductivity of 1.01 x 10^{-5} cm/s reported by Titan (1994a), and is within the range of 5 to 10 feet per year (ft/yr) [approximately 5 x 10^{-6} cm/s to 1 x 10^{-5} cm/s] reported by Dames and Moore (1978b) for the (saturated) perched zone during the initial site investigation.

Because of the generally low permeability of the perched zone beneath the site, well yields are typically low (generally less than 0.5 gpm). Many of the perched monitoring wells purge dry and take several hours to more than a day to recover sufficiently for groundwater samples to be collected. Sufficient productivity can generally be obtained only in areas where the saturated thickness is greater, which is the primary reason that the perched zone has been used on a limited basis as a water supply to the north (upgradient) of the site, but has not been used downgradient of the site. Within areas on the east side of the site that have greater saturated thicknesses due to proximity to the two northern wildlife ponds, and that intercept the higher permeability materials associated with the chloroform plume, well yields of as much as 4 gpm were achievable. However, since water delivery to the two northern wildlife ponds ceased in 2012, saturated thicknesses and well productivities in this area have diminished. As of the fourth quarter of 2015, sustainable, average pumping rates at chloroform and nitrate pumping wells ranged from less than 0.1 to approximately 1 gpm

1.5.1.4 Perched Groundwater Flow

Perched groundwater flow at the site is generally from northeast to southwest. Figure 1.5-3 displays the local perched groundwater elevation contours at the Mill, as measured in the first quarter of 2016. Depression of the perched water table occurs near chloroform pumping wells MW-4, MW-26, TW4-1, TW4-2, TW4-4, TW4-11, TW4-19, TW4-20, TW4-21, TW4-22 and TW4-37, and near nitrate pumping wells TW4-22, TW4-24, TW4-25, and TWN-2. These wells are pumped to reduce chloroform and nitrate mass in the perched zone east and northeast of the tailings cells. As shown on Figure 1.5-3, beneath and south of the tailings management cells, in the west central portion of the site, perched water flow is south-southwest to southwest. Flow on the western margin of the mesa is generally south, approximately parallel to the rim (where the Burro Canyon Formation [and perched water zone] is terminated by erosion). On the eastern side of the site perched water flow is also generally to the south. Because of mounding near wildlife ponds, flow direction ranges locally from westerly (west of the ponds) to easterly (east of the ponds).

Dry areas in the perched zone southwest of the tailings management cells occur along the structural high in the Brushy Basin Member/Burro Canyon Formation contact that extends from beneath tailings cell 4B southwest to the vicinity of abandoned boring DR-18. In places along this structural high the contact rises above the perched water elevation creating the dry areas shown on Figure 1.5-3.

An apparent groundwater divide occurs west of Cell 4B near DR-2. Water north of the apparent divide flows primarily north-northeast to Westwater Seep and water south of the apparent divide flows south toward Ruin Spring.

Perched zone hydraulic gradients currently range from a maximum of approximately 0.096 ft/ft east of tailings cell 2 (north of pumping well TW4-11) to approximately 0.0042 ft/ft west-southwest of Cell 4B (between DR-7 and DR-5). The overall average site hydraulic gradient of approximately 0.011 ft/ft (between TWN-19 and Ruin Spring) is similar to the average hydraulic gradient downgradient of the tailings management cells of approximately 0.012 ft/ft (between MW-37 and Ruin Spring).

1.5.1.5 Perched Zone Hydrogeology Beneath and Downgradient of The Tailings Management Cells

Based on measurements at non-pumping wells, 1st Quarter, 2016 perched water depths ranged from approximately 32 feet in the northeastern portion of the site (adjacent to the wildlife ponds) to approximately 114 feet at the southwest margin of Cell 3 (Figure 1.5-4). Based on measurements at non-pumping wells, 1st Quarter, 2016 perched zone saturated thicknesses ranged from approximately 83 ft in the northeast portion of the site to less than 1 ft in the southwest portion of the site (Figure 1.5-5). The relatively large saturated thicknesses in the northeastern portion of the site are related to past seepage from the northern wildlife ponds located northeast of the tailings management cells.

Water levels in DR-22 and chloroform pumping well TW4-11 are below the top of the Brushy Basin Member, yielding saturated thicknesses of zero. Casings in DR-22 and TW4-11 extend approximately 2.5 feet and 11.5 feet, respectively, below the Brushy Basin Member contact. Although water is present in the bottom of the DR-22 casing, the level is below the Brushy Basin contact. The water level in TW4-11 is maintained at or below the Brushy Basin contact by pumping.

Areas of small saturated thickness (less than 5 feet) occur west and southwest of the tailings management cells. As shown in Figures 1.5-4 and 1.5-5, an area of small saturated thickness extends between Westwater Seep and the southwest portion of Cell 4B, encompassing DR-6 and DR-10. As discussed in HGC (2014), perched water flows westward from the area of the tailings cells through the area of low saturated thickness between DR-6 and DR-10, into an area having saturated thicknesses several times larger than at DR-6 and DR-10. The transmissivity (the product of hydraulic conductivity and saturated thickness) of the area of low saturated thickness is two to three orders of magnitude lower than for the area of larger saturated thickness to the west (near DR-2 [abandoned], DR-5, and DR-9). Water flows out of the area of larger saturated thickness (near DR-2 [abandoned] and DR-5) to the northeast toward known discharge point Westwater Seep and to the south through a paleovalley in the Brushy Basin Member surface towards known discharge point Ruin Spring. The relationship between perched water and seeps and springs is discussed in more detail in Section 1.5.2.

Darcy's Law calculations presented in HGC (2014) indicate that an additional water source is needed to maintain the relatively large saturated thicknesses west of the area of low saturated thickness encompassing DR-6 and DR-10; otherwise Westwater Seep and the paleovalley to the south would drain the area of larger saturated thickness more quickly than water was supplied. The most likely source of additional water to the area of larger saturated thickness is infiltration of precipitation.

As discussed above, perched zone hydraulic gradients currently range from a maximum of approximately 0.096 feet per foot (ft/ft) east of Cell 2 to approximately 0.0042 ft/ft west-southwest of the tailings management cells, between DR-7 and DR-5. The average hydraulic gradient between the downgradient edge of tailings Cell 4B and Ruin Spring is approximately 0.012 ft/ft, similar to the overall site hydraulic gradient (between TWN-19 and Ruin Spring) of approximately 0.011 ft/ft. The combination of relatively low hydraulic conductivities (geometric average of approximately 1 x 10^{-5} cm/s) and relatively flat hydraulic gradients downgradient of the tailings management cells imply small groundwater velocities and large travel times.

1.5.2 Seep and Spring Occurrence and Hydrogeology

Perched groundwater discharges in seeps and springs located to the west, south, east, and southeast of the site along the margins of White Mesa.

All seeps and springs examined have associated cottonwood trees that suggest a relatively consistent source of water. Seeps and springs occurring at the margins of White Mesa are typically associated with sandstones of the Burro Canyon Formation, except Cottonwood Seep, which is associated with the lower portion of the Brushy Basin Member of the Morrison Formation. Figure 1.5-6 shows the December 2009 surveyed locations of seeps and springs and the Frog Pond. As shown on Figure 1.5-6, all springs and seeps are located within drainages, and except for Cottonwood Seep, are located at the mesa margins. Table 1.5-1 provides surveyed locations and elevations of the seeps and springs and the Frog Pond. The December 2009 seep and spring survey data shown in Table 1.5-1 were used in subsequent reporting where seep and spring locations and elevations were relevant.

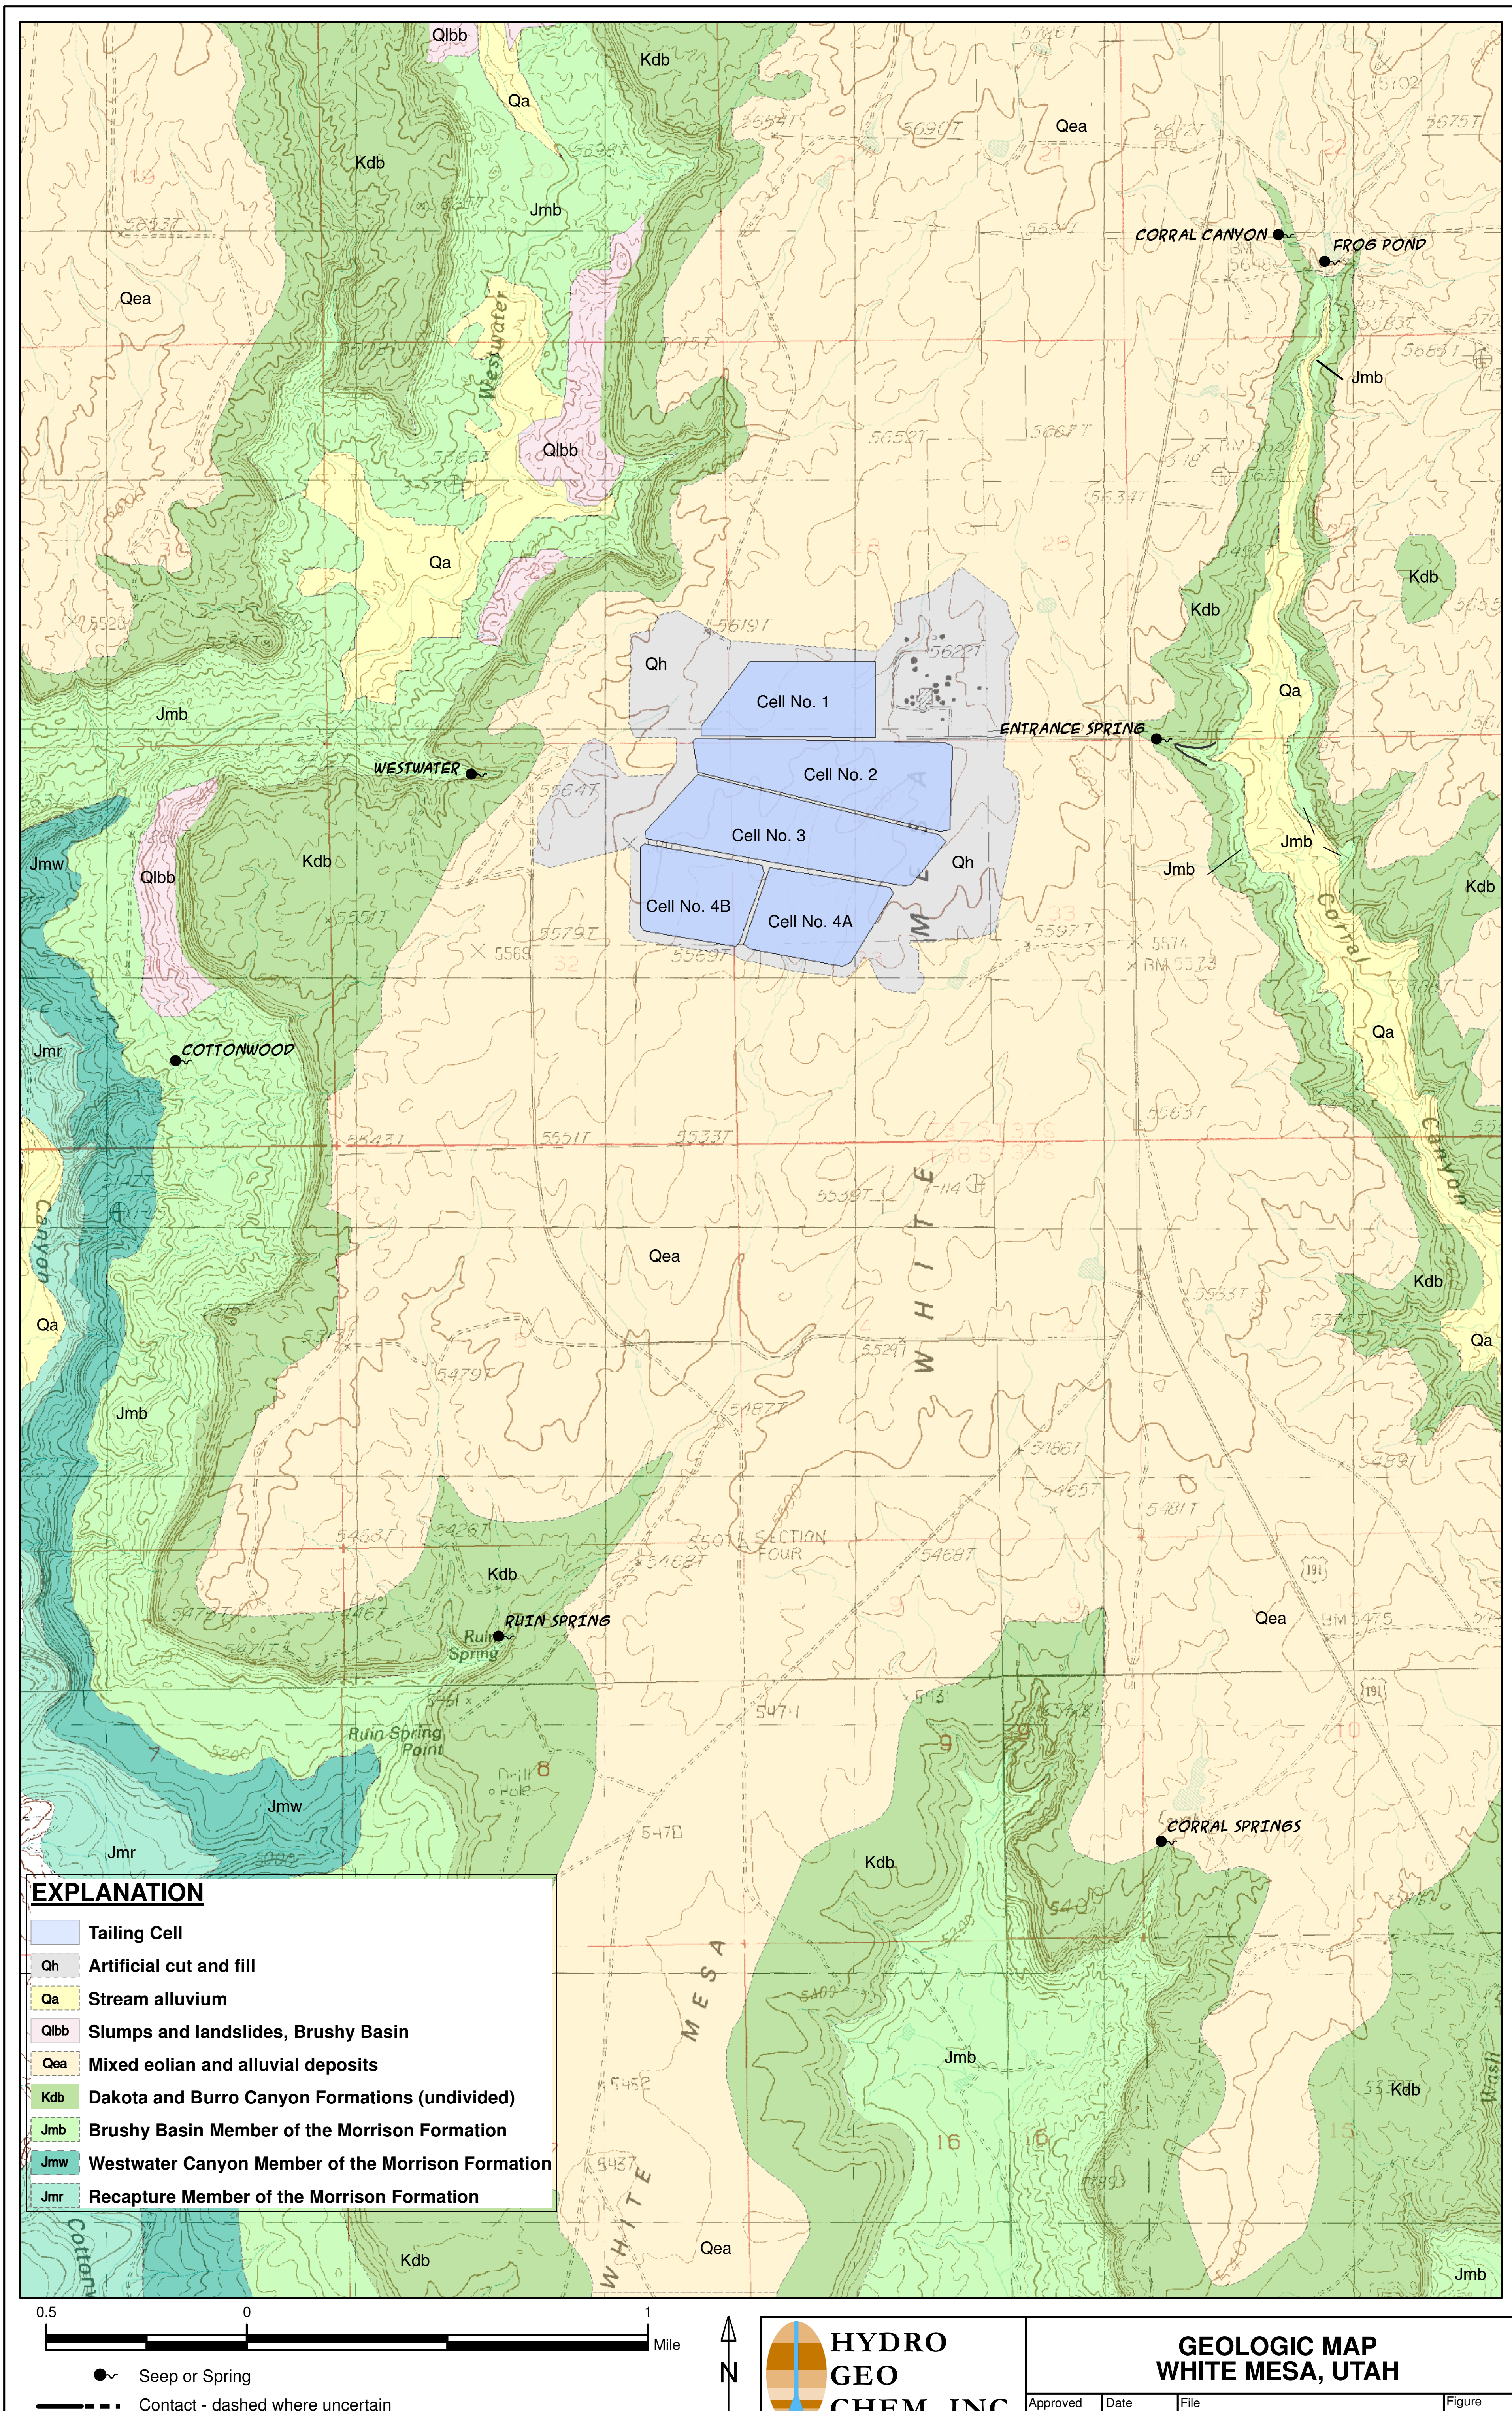
As discussed in Section 1.1.5.4, Figure 1.5-3 shows first quarter 2016 perched water level contours and the locations and elevations of seeps and springs. Perched water level contours are based on water levels measured in the perched groundwater monitoring wells shown on Figure 1.5-3, and include elevations of all seeps and springs except Cottonwood Seep. Based on Figure 1.5-3, Corral Canyon Seep is located upgradient of the tailings management cells, and Entrance Spring and Corral Springs are located cross gradient of the tailings management cells. Both Entrance Spring and Corral Springs are separated from the tailings management cells by a groundwater divide. Westwater Seep is the closest discharge point west of the tailings management cells and Ruin Spring is the closest discharge point south-southwest of the tailings management system. Ruin Spring is located downgradient of approximately the southeastern 2/3 of the tailings management system, and Westwater Seep appears to be downgradient of approximately the northwestern 1/3 of the tailings management system. Cottonwood Seep is neither cross gradient nor downgradient of the tailings management cells because it is interpreted to receive water from a source other than the perched groundwater system hosted by the Burro Canyon Formation.

The relationship between seeps and springs and the geology of White Mesa are shown on Figure 1.5-7. The geology on Figure 1.5-7 is based on Kirby (2008) and Hintze, et al. (2000), and has been modified locally by field reconnaissance. The Burro Canyon Formation and the Dakota Sandstone are undifferentiated on the geologic map. As shown on Figure 1.5-7, all seeps and springs except Cottonwood Seep are associated with outcrops of the Burro Canyon Formation (and/or Dakota Sandstone). Some are also associated with mixed eolian and alluvial deposits stratigraphically above the Burro Canyon Formation and/or Dakota Sandstone. Ruin Spring and Westwater Seep are located at the contact between the Burro Canyon Formation and underlying Brushy Basin Member. Westwater Seep (where typically sampled) occurs within alluvium at the Burro Canyon Formation/Brushy Basin Member contact whereas Ruin Spring occurs at the contact but above the alluvium in the associated drainage. Corral Canyon Seep, Entrance Spring, and Corral Springs occur within alluvium near the contact of the alluvium with the Burro Canyon Formation, but at an elevation above the contact between the Burro Canyon Formation and Brushy Basin Member. In contrast, Cottonwood Seep is mapped within the Brushy Basin Member, approximately 1,500 feet west of the termination of the Burro Canyon Formation at the western mesa rim, and stratigraphically more than 200 feet below the contact between the Burro Canyon Formation and Brushy Basin Member.

The Burro Canyon Formation (and perched water zone) does not exist at Cottonwood Seep because it has been eroded. Cottonwood Seep is interpreted to receive water primarily from a source stratigraphically below the Burro Canyon Formation and from a hydrogeologic system other than the perched water system at the site. The primary source of Cottonwood Seep (and “2nd Seep” immediately to the north of Cottonwood Seep) is interpreted to be coarser-grained materials within the lower portion of the Brushy Basin Member or upper portion of the Westwater Canyon Member.



Geological Map of the Blanding Area, San Juan County, Utah (modified from Haynes et al., 1962; Dames & Moore, 1978 and Kirby, 2008)
Base Map Prepared from Portions of the Blanding South, Black Mesa Butte, Big Bench and No Mans Land U.S.G.S. 7.5' Quadrangles.

Springs occurring within alluvium deposited within drainages cutting the Burro Canyon Formation may or may not receive a contribution from perched water. Except for Ruin Spring (and "2nd Seep" immediately to the north of Cottonwood Seep), each spring and seep occurs in alluvial materials within a drainage that will supply surface water during wet periods and help to recharge any alluvial materials within the drainage as well as bedrock near the drainage. Westwater Seep, Corral Canyon Seep, Entrance Spring, and Corral Springs may therefore receive water from both alluvial and bedrock (perched water) sources. Corral Springs, located immediately downgradient of a stock pond, may receive water primarily from alluvium recharged from the stock pond. Any alluvial materials within the drainage or marginal bedrock that are recharged during precipitation events will likely, at least temporarily, yield water to the seeps.

HGC (2014) discusses the potential for enhanced recharge from precipitation along the mesa margins where Dakota Sandstone and/or Burro Canyon Formation are exposed by erosion. Such recharge is expected to temporarily enhance flow at nearby seeps and springs draining the Burro Canyon Formation and/or Dakota Sandstone. The area of increased saturated thickness west of DR-6 and DR-10 is likely the result of recharge enhanced by the direct exposure of weathered Dakota Sandstone and Burro Canyon Formation, and the thinness or absence of any overlying low permeability materials such as the Mancos Shale (Figure 1.5-7).

Although seep and spring elevations (except Cottonwood Seep) have been included in perched water level contour maps (such as Figure 1.5-3) since the HGC (2010b) investigation, the assumption that the seep or spring elevation is representative of the perched water elevation is likely to be correct only in cases where the feature receives most or all of its flow from the perched water, and where the supply is relatively continuous (for example, Ruin Spring). The uncertainty that results from including seeps and springs in the contouring of perched water levels must be considered when interpreting perched water level data.

Using amethod similar to that presented in HGC (2009a), perched water pore velocities and travel times between the tailings management cells and Ruin Spring and between the tailings management cells and Westwater Seep were calculated in HGC (2014) using first Quarter 2014 water levels. As discussed in more detail in HGC (2014), the calculated travel times between the downgradient margin of cell 4B and Ruin Spring range from approximately 10,650 to 19,650 years. The calculated travel time between the southwest corner of Cell 3 to Westwater Seep is approximately 3,230 years.

1.5.3 Groundwater Quality

1.5.3.1 Entrada/Navajo Aquifer

The Entrada and Navajo Sandstones are relatively prolific aquifers beneath and in the vicinity of the site. Water wells at the site are screened in both of these units, and for the purposes of this discussion they will be treated as a single aquifer. Water in the Entrada/Navajo Aquifer is under artesian pressure, rising 800 to 900 ft above the top of the Entrada's contact with the overlying Summervillle Formation; static water levels are 390 to 500 ft below ground surface.

Within the region, this aquifer is capable of yielding domestic quality water at rates of 150 to 225 gpm. For that reason, it serves as a secondary source of water for the Mill. Additionally, two domestic water supply wells drawing from the Entrada/Navajo Aquifer are located 4.5 miles southeast of the Mill site on the Ute Mountain Ute Reservation. Although the water quality and productivity of the Navajo/Entrada aquifer are generally good, the depth of the aquifer (greater than1,000 ft bls) makes access difficult.

Table 1.5-2 is a tabulation of groundwater quality of the Navajo Sandstone aquifer as reported in the FES and subsequent sampling. TDS ranges from 216 to 1,110 mg/l in three samples taken over a period from January 27, 1977, to May 4, 1977. High iron concentrations are found in the Navajo Sandstone. Because the Navajo Sandstone aquifer is isolated from the perched groundwater zone by approximately 1,000 to 1,100 ft of materials having a low average vertical permeability, sampling of the Navajo Sandstone is not required under the Mill's previous NRC Point of Compliance monitoring program or under the GWDP. However, samples were taken at two other deep aquifer wells (#2 and #5) on site (see Figure 1.5-8 for the locations of these wells), on June 1, 1999 and June 8, 1999, respectively, and the results are included in Table 1.5-2.

1.5.3.2 Perched Groundwater Zone

Perched groundwater in the Dakota/Burro Canyon Formation is used on a limited basis to the north (upgradient) of the site because the saturated thickness generally increases to the north of the site and it is more easily accessible than the Entrada/Navajo aquifer. The quality of the perched water at the site is generally poor and extremely variable. As of the first quarter of 2016, the concentrations of TDS measured in water sampled from upgradient and downgradient wells range between approximately 1,000 and 8,300 mg/1. Sulfate concentrations measured in far upgradient wells MW-1, MW-18 and MW-19 ranged from 580 and 2,000 mg/l, and across the site sulfate varied from 430 mg/L to 6,570 mg/L. The perched groundwater therefore is used primarily for stock watering and irrigation. Section 1.5.3 below provides a more detailed discussion of background groundwater quality in the perched aquifer.

1.5.4 Background Groundwater Quality in the Perched Aquifer

A significant amount of historical groundwater quality data has been collected by EFRI and previous operators of the Mill for many wells at the facility.

At the time of original issuance of the GWDP, the Director had not yet completed an evaluation of the historical data, particularly with regard to data quality, and quality assurance issues. The Director also noted several groundwater quality issues that needed to be resolved prior to a determination of background groundwater quality at the site, such as a number of constituents that exceeded their respective Groundwater Quality Standard ("GWQS") and long-term trends in uranium in downgradient wells MW-14, MW-15 and cross-gradient well MW-17, and a spatial high of uranium in those three wells.

As a result of the foregoing, the Director required that an Existing Well Background Report (INTERA, 2007a) be prepared to address and resolve these issues. Prior to the approval of the Existing Well Background Report, GWCLs were set in Table 2 of the GWDP as 0.25 and 0.5 times the GWQS for Class II and III groundwater respectively.

The Director reviewed the Existing Well Background Report and GWCLs that reflect background groundwater quality were set for all monitoring wells except newly installed MW-35, MW-36, and MW-37. Background data collected for the establishment of GWCLs that reflect background groundwater quality at MW-35, MW-36 and MW-37 were being collected at that time and were subsequently provided in INTERA (2014c).

As required by the GWDP, the Existing Well Background Report addressed all available historical data, which included pre-operational and operational data, for the compliance monitoring wells under the GWDP that existed at the date of issuance of the GWDP. The Regional Background Report (INTERA, 2007b) focused on pre-operational site data and available regional data to develop the best available set of background data that could not conceivably have been influenced by Mill operations. The New Well Background Report (INTERA 2008), which was required by Part I.H.4 of a previous revision of the GWDP, analyzed the data collected from wells MW-3A, MW-23, MW-24, MW-25, MW-27, MW-28, MW-29, MW-30 and MW-31 (the "new" wells), which were installed in 2005, to determine background concentrations for constituents listed in the GWDP for each new well.

The purpose of the Existing Well Background Report and the New Well Background Report was to satisfy several objectives. First, in the case of the Existing Well Background Report, to perform a quality assurance evaluation and data validation of the existing and historical on-site groundwater quality data in accordance with the requirements of Part I.H.3 of a previous revision of the GWDP, and to develop a database consisting of historical groundwater monitoring data for "existing" wells and constituents.

Second, in the case of the New Well Background Report, to compile a database consisting of monitoring results for new wells, which were collected subsequent to issuance of the GWDP, in accordance with the Mill's Groundwater Quality Assurance Plan ("QAP") data quality objectives.

Third, to perform a statistical, temporal and spatial evaluation of the existing well and new well data bases to determine if there have been any impacts to groundwater from Mill activities. Since the Mill is an existing facility that has been in operation since 1980, such an analysis of historical groundwater monitoring data was required in order to ensure that the monitoring results to be used to determine background groundwater quality at the site establish GWCLs that have not been impacted by Mill activities.

Finally, in the event the analysis demonstrates that groundwater has not been impacted by Mill activities, to develop a GWCL for each constituent in each well.

The Regional Background Report was prepared as a supplement to the Existing Well Background Report to provide further support to the conclusion that Mill activities have not impacted groundwater.

In evaluating the historical data for the existing wells, INTERA used the following approach:

- If historical data for a constituent in a well do not demonstrate a statistically significant upward trend (or downward trend in pH), then the proposed GWCL for that constituent is accepted as representative of background, regardless of whether or not the proposed GWCL exceeds the GWQS for that constituent. This is because the monitoring results for the constituent can be considered to have been consistently representative since commencement of Mill activities or installation of the well; and
- If historical data for a constituent in a monitoring well represent a statistically significant upward trend (or downward trend in the case of pH), then the data is further evaluated to determine whether the trend is the result of natural causes or Mill activities. If it is concluded that the trend results from natural causes, then the GWCL proposed in the Existing Well Background Report will be appropriate.

After applying the foregoing approach, INTERA concluded that, other than some detected chloroform and related organic contamination at the Mill site, which is the subject of a separate investigation and corrective action, and that is the result of pre-Mill activities, there have been no impacts to groundwater from Mill activities.

In reaching this conclusion, INTERA noted that, even though there are a number of increasing trends in various constituents at the site, none of the trends are caused by Mill activities for the following reasons:

- Chloride is unquestionably the best indicator parameter, and there are no significant trends in chloride which are attributable to Mill activities in any of the wells
- There are no noteworthy correlations between chloride and uranium in wells with increasing trends in uranium, other than in far upgradient wells MW-19 and MW-18, which INTERA concluded are not related to potential tailings seepage. MW-18 and MW-19 cannot have been impacted because they are located more than 2,200 feet northeast (upgradient) of the tailings management system and perched water elevations in these wells are approximately 15 to 25 feet higher than perched water elevations beneath the northeast (upgradient) corner of the tailings management cells. INTERA noted that it is inconceivable to have an increasing trend in any other parameter caused by seepage from the Mill tailings without a corresponding increase in chloride

- There are significant increasing trends far upgradient in MW-1, MW-18 or MW-19 in uranium, sulfate, TDS, iron, selenium, thallium, ammonia and fluoride and far downgradient in MW-3 in uranium and selenium, sulfate, TDS and pH (decreasing trend). INTERA concluded that these data provide very strong evidence that natural site phenomena are the cause of increasing trends in these constituents (decreasing with respect to pH) in other site wells and that these data also support the conclusion that natural phenomena are the cause of increasing trends in other constituents
- On a review of the spatial distribution of constituents, it is quite apparent that the constituents of concern are dispersed across the site and not located in any systematic manner that would suggest tailings leakage.

INTERA concluded that, after extensive analysis of the data, and given the conclusion that there have been no impacts to groundwater from Mill activities, the proposed GWCLs set out in Table 16 of the Existing Well Background Report are appropriate, and are indicative of background perched groundwater quality. INTERA did advise, however, that proposed GWCLs for all the trending constituents should be re-evaluated upon GWDP renewal to determine if they are still appropriate at the time of renewal.

In the New Well Background Report, INTERA followed the same approach used in the Existing Well Background Report for evaluating the existing well data. In addition, INTERA compared the groundwater monitoring results for the new wells to the results for the existing wells analyzed in the Existing Well Background Report and to the pre-operational and regional results analyzed in the Regional Background Report. This was particularly important for analysis of the new wells because available historical analytical data for constituents in those wells post-date the commencement of Mill operations. Available data for the new wells may not be sufficient to identify long-term constituent trends. By comparing the means for the constituents in the new wells to those for existing well and regional background data, INTERA was able to determine if the concentrations of constituents in the new wells were consistent with site background.

After applying the foregoing approach, INTERA concluded that the new monitoring wells were not impacted by Mill activities. INTERA also concluded that the new well groundwater monitoring results were consistent with the existing well results provided in the Existing Well Background Report and consistent with the pre-operational and regional well, seep and spring results provided in the Regional Background Report. INTERA noted some detections of chloroform and related organic contamination and degradation products and nitrate and nitrite in the new wells, which are the subject of separate investigations and corrective actions, but that such contamination was the result of pre-Mill activities. Corrective actions for nitrate and chloroform, respectively, are described in: *Nitrate Corrective Action Plan* (CAP), [HGC, 2012a]; and *Groundwater Corrective Action Plan* (GCAP) found in Attachment 1, of the final Stipulation and Consent Order Docket No. UGW20-01, approved on September 14, 2015 by the Utah Department of Environmental Quality Division of Waste Management and Radiation Control (DWMRC) [Utah Department of Environmental Quality Division of Solid Waste and Radiation Control, 2015]).

Given its conclusion that there were no impacts to groundwater from Mill activities, INTERA concluded that the proposed GWCLs for new wells set out in Table 10 of the New Well Background Report were appropriate, and indicative of background perched groundwater quality. Again, INTERA noted that GWCLs for trending constituents should be re-evaluated upon GWDP renewal to determine if they are still appropriate at the time of renewal.

Subsequent investigation of nitrate delineated the nitrate plume and indicated that ammonium sulfate handling in the vicinity of the ammonium sulfate crystal tanks (southeast of well TWN-2) is potentially a source of nitrate to the nitrate plume. There are no known current unidentified or unaddressed sources of the nitrate plume. There appear to have been a number of known and potential historical sources; however, it has not been possible to confirm or quantify the contribution of each source. The conclusion that there were no impacts to perched groundwater from Mill activities has therefore been modified to include a potential contribution to the nitrate plume from Mill and non-mill sources. However, the conclusion that there have been no impacts to perched groundwater from the tailings management system operation is valid.

During the course of discussions with EFRI staff, and further DWMRC review, DWMRC supplemented the analysis provided in the Background Reports by commissioning the University of Utah to perform a geochemical and isotopic groundwater study at the Mill, described in *Summary of work completed, data results, interpretations and recommendations for the July 2007 Sampling Event at the Denison Mines, USA, White Mesa Uranium Mill Near Blanding Utah*, May 2008, prepared by T. Grant Hurst and D. Kip Solomon, Department of Geophysics, University of Utah (the "University of Utah Study" [University of Utah, 2008]). The purpose of the University of Utah Study was to evaluate whether the increasing and elevated trace metal concentrations (such as uranium) found in the monitoring wells at the Mill were due to potential leakage from the on-site tailings management cells. To investigate this potential problem, the study examined groundwater flow, chemical composition, noble gas and isotopic composition, and age of the on-site groundwater. Similar evaluations were also made on samples of the tailings wastewater and nearby surface water stored in the northern wildlife ponds at the facility. Fieldwork for the University of Utah Study was conducted July 17 - 26, 2007. The conclusions in the University of Utah Study supported EFRI's conclusions in the Background Reports that tailings management cells had not impacted groundwater.

Upon approval of the GWDP in 2010, constituents with two consecutive GWCL exceedances were subject to a Source Assessment Report (SAR) as defined in the GWDP. The initial SAR was submitted in October of 2012 (INTERA 2012a) and covered the constituents in wells with consecutive exceedances since the approval of the GWDP in 2010. The October 2012 SAR (INTERA 2012a) presented a geochemical analysis of parameters that exhibited exceedances as well as an analysis of the indicator parameters in each of those wells to determine if the exceedance could be related to potential tailings seepage or Mill-related activities. Since then, additional SARs that include INTERA 2013a, 2013b, 2014a, 2014b, and 2015 cover additional consecutive exceedances. In all cases the exceedances for which the SARs were performed were determined to result from naturally occurring conditions in the groundwater at the site or from other factors that are affecting groundwater but are unrelated to Mill operation. These other factors include the nitrate/chloride plume that is addressed by the nitrate CAP and the site-wide decline in pH that was identified at the time of the Background Report.

With regard to the decline in pH, background analysis and determination of GWCLs for pH were performed using laboratory pH measurements rather than using measurements that are collected in the field at the time of sampling by using a pH probe. Since the latter of these two methods of measuring pH is more reliable, an additional pH analysis was performed in 2012 using only field data. GWCLs for pH were recalculated at this time using the field measurements (INTERA, 2012b). EFRI compared the Mill's groundwater pH data from the second quarter of 2011 and noted that *all* of the June 2011 groundwater results, and many of the other results from the second quarter of 2011, were already outside the revised GWCLs that were to be proposed. Pursuant to teleconferences with DWMRC on December 5, and December 19, 2011, EFRI submitted a Work Plan and Schedule on January 20, 2012 and a revised plan based on DWMRC comments on April 13, 2012. Based on the approved Work Plan and Time Schedule, EFRI and DWMRC entered into a Stipulated Consent Agreement ("SCA") dated July 12, 2012. The SCA required the completion of the pH Report (INTERA, 2012b) and the Pyrite Investigation and associated report (HGC, 2012c). The pH Report and Pyrite Investigation Report were submitted to DWMRC on November 9, 2012 and December 7, 2012 respectively. By letter dated April 25, 2013, DWMRC accepted the conclusions that the out-of-compliance results for pH are due to background effects within the aquifer matrix and are not caused by Mill activities. DWMRC also approved the recalculation of the GWCLs.

HGC (2012c) determined that pH decreases resulted primarily from pyrite oxidation enhanced by oxygen delivery to the perched zone. Pyrite exists naturally in the Burro Canyon Formation and Dakota Sandstone, and is present both above and below the perched water table. Oxygen delivery mechanisms include diffusive and advective gas-phase transport to the Burro Canyon Formation and /or Dakota Sandstone in the vicinities of perched wells via perched well screens, and advective liquid-phase transport dissolved in wildlife pond seepage. HGC (2012c) and HGC (2014) also noted that pyrite may be degraded by nitrate present in the perched water. Pyrite oxidation by either mechanism may release acid and sulfate. The site-wide pH decreases were therefore determined to be unrelated to tailings management cell operation.

1.5.5 Quality of Groundwater at the Compliance Monitoring Point

Analytical results from groundwater sampling are reported quarterly in Groundwater Monitoring Reports, which are filed with the Director pursuant to Part I.F.1 of the GWDP.

1.5.6 Springs and Seeps

As discussed in Section 1.5.1.4, perched groundwater at the Mill site discharges in springs and seeps along Westwater Creek Canyon and Cottonwood Canyon to the west-southwest of the site, and along Corral Canyon to the east of the site, where the Burro Canyon Formation outcrops. Water samples have been collected and analyzed from springs and seeps in the Mill vicinity as part of the baseline field investigations reported in the 1978 ER (See Table 2.6-6 in Dames & Moore, 1978).

During the period 2003-2004, EFRI implemented a sampling program for seeps and springs in the vicinity of the Mill which had been sampled in 1978, prior to the Mill’s construction. Four locations were designated for sampling (shown on Figure 1.5-8). These are Ruin Spring (G3R), Cottonwood Seep (G4R), west of Westwater Creek (G5R) and Corral Canyon (G1R). During the 2-year study period only two of the four locations were able to be sampled, Ruin Spring and Cottonwood Canyon. The other two locations, Corral Creek and the location west of Westwater Creek were not flowing (seeping) and samples could not be collected. With regard to the Cottonwood seep, while water was present, the volume was not sufficient to complete all determinations, and only organic analyses were conducted. The results of the organic analysis did not detect any detectable organics.

Samples at Ruin Spring were analyzed for major ions, physical properties, metals, radionuclides, volatile and semi-volatile organic compounds, herbicides and pesticides, and synthetic organic compounds. With the exception of one chloromethane detection, organic determinations were at less than detectable concentrations and are not shown in Table 1.5-3. The detection of chloromethane is not uncommon in groundwater and can be due to natural sources. In fact, chloromethane has been observed by EFRI at detectable concentrations in field blank samples during routine groundwater sampling events.

The results of the 2003/2004 sampling for the other parameters tested are shown in Table 1.5-3. The results of the sampling did not indicate the presence of Mill-derived groundwater constituents and are representative of background conditions.

Source: Table 3.7-9 of 2007 ER.

During 2009, the Mill implemented an annual sampling program for seeps and springs. The seeps and springs sampling program is included in the Sampling Plan for Seeps and Springs in the Vicinity of the White Mesa Uranium Mill Revision: 0, March 17, 2009 (and as submitted to UDEQ for approval, Draft Sampling Plan for Seeps and Springs, Revision 1, June 10, 2011). The annual sampling program for seeps and springs requires sampling once per year at the four seeps and springs described above, plus a fifth seep, Corrals Seep, to the extent water flow is sufficient for sampling. Samples were collected in July 2009; August and November 2010; May and July 2011, June 2012, July 2013, June 2014; and June 2015. Under the Plan only springs and seeps that had sufficient water flow were selected for sampling. The results of the annual sampling are shown in Table 1.5-4.

1.5.7 Groundwater Appropriations Within a Five Mile Radius

Two hundred sixty one groundwater appropriation applications, within a five-mile radius of the Mill site, are on file with the Utah State Engineer's office. A summary of the applications is presented in Table 1.5-5 and shown on Figure 1.5-9. The majority of the applications are by private individuals and for wells drawing small, intermittent quantities of water, less than eight gpm, from the Burro Canyon formation. For the most part, these wells are located upgradient (north) of the Mill site. Domestic water, stock watering, and irrigation are listed as primary uses of the majority of the wells. It is important to note that no water supply wells completed in the perched groundwater of the Burro Canyon formation exist directly downgradient of the site within the five-mile radius. Two water supply wells, which available data indicate are completed in the Entrada/Navajo sandstone, exist approximately 4.5 miles southeast of the site on the Ute Mountain Ute Reservation. These wells supply domestic water for the Ute Mountain Ute White Mesa Community, situated on the mesa along Highway 191 (see Figure 1.5-9). Data supplied by the Tribal Environmental Programs Office indicate that both wells are completed in the Entrada/Navajo sandstone, which is approximately 1,200 feet below the ground surface. Insufficient data are available to define the groundwater flow direction in the Entrada/Navajo sandstone in the vicinity of the Mill.

The yield from wells completed in the Burro Canyon formation within the White Mesa site is generally lower than that obtained from wells in this formation upgradient of the site. For the most part, the documented sustainable pumping rates from on-site wells completed in the Burro Canyon formation are typically less than 1/2 gpm. Even at low pumping rates, on-site wells completed in the Burro Canyon formation are typically pumped dry within a couple of hours, and corrective action pumping wells have to be cycled on and off due to the low productivity.

This low productivity suggests that the Mill is located over a peripheral fringe of perched water, with saturated thickness in the perched zone discontinuous and generally decreasing beneath the site, and with conductivity of the formation being very low. These observations have been verified by studies performed for the U.S. Department of Energy's disposal site at Slick Rock, which noted that the Dakota Sandstone, Burro Canyon formation, and upper claystone of the Brushy Basin Member are not considered aquifers due to the low permeability, discontinuous nature, and limited thickness of these units (U.S. DOE, 1993).

1.6 Geology

The following text is copied, with minor revisions, from the 1978 ER (Dames and Moore, 1978b). The text has been included here for ease of reference and to provide background information concerning the site geology. 1978 ER subsections used in the following text are shown in parentheses immediately following the subsection titles.

The site is near the western margin of the Blanding Basin in southeastern Utah and within the Monticello uranium-mining district. Thousands of feet of multi-colored marine and non-marine sedimentary rocks have been uplifted and warped, and subsequent erosion has carved a spectacular landscape for which the region is famous. Another unique feature of the region is the wide-spread presence of unusually large accumulations of uranium-bearing minerals.

1.6.1 Regional Geology

The following descriptions of regional physiography; rock units; and structure and tectonics are reproduced from the 1978 ER for ease of reference and as a review of regional geology.

1.6.1.1 Physiography (1978 ER Section 2.4.1.1)

The Mill site lies within the Canyon Lands section of the Colorado Plateau physiographic province. To the north, this section is distinctly bounded by the Book Cliffs and Grand Mesa of the Uinta Basin; western margins are defined by the tectonically controlled High Plateaus section, and the southern boundary is arbitrarily defined along the San Juan River. The eastern boundary is less distinct where the elevated surface of the Canyon Lands section merges with the Southern Rocky Mountain province.

Canyon Lands has undergone epeirogenic uplift and subsequent major erosion has produced the region's characteristic angular topography reflected by high plateaus, mesas, buttes, structural benches, and deep canyons incised into flat-laying sedimentary rocks of pre-Tertiary age. Elevations range from approximately 3,000 feet (914 meters) in the bottom of the deeper canyons along the southwestern margins of the section to more than 11,000 feet (3,353 meters) in the topographically anomalous laccolithic Henry, Abajo and La Sal Mountains to the northeast. Except for the deeper canyons and isolated mountain peaks, an average elevation in excess of 500 feet (1,524 meters) persists over most of the Canyon Lands section.

On a more localized regional basis, the Mill site is located near the western edge of the Blanding Basin, sometimes referred to as the Great Sage Plain (Eardly, 1958), lying east of the north-south trending Monument Uplift, south of the Abajo Mountains and adjacent to the northwesterly-trending Paradox Fold and Fault Belt (Figure 1.6-1). Topographically, the Abajo Mountains are the most prominent feature in the region, rising more than 4,000 feet (1,219 meters) above the broad, gently rolling surface of the Great Sage Plain.

The Great Sage Plain is a structural slope, capped by the resistant Burro Canyon formation and the Dakota Sandstone, almost horizontal in an east-west direction but descends to the south with a regional slope of about 2,000 feet (610 meters) over a distance of nearly 50 miles (80 kilometers). Though not as deeply or intricately dissected as other parts of the Canyon Lands, the plain is cut by numerous narrow and vertical-walled south-trending valleys 100 to more than 500 feet (30 to 152+ meters) deep. Water from the intermittent streams that drain the plain flow southward to the San Juan River, eventually joining the Colorado River and exiting the Canyon Lands section through the Grand Canyon.

1.6.1.2 Rock Units (1978 ER Section 2.4.1.1)

The sedimentary rocks exposed in southeastern Utah have an aggregate thickness of about 6,000 to 7,000 feet (1,829 to 2,134 meters) and range in age from Pennsylvanian to Late Cretaceous. Older unexposed rocks are known mainly from oil well drilling in the Blanding Basin and Monument Uplift. These wells have encountered correlative Cambrian to Permian rock units of markedly differing thicknesses but averaging over 5,000 feet (1,524 meters) in total thickness (Witkind, 1964). Most of the wells drilled in the region have bottomed in the Pennsylvanian Paradox Member of the Hermosa formation. A generalized stratigraphic section of rock units ranging in age from Cambrian through Jurassic and Triassic (?), as determined from oil-well logs, is shown in Table 1.6-1. Descriptions of the younger rocks, Jurassic through Cretaceous, are based on field mapping by various investigators and are shown in Table 1.6-2.

Era	Age	Stratigraphic Unit	Thickness* (ft.)	Description
MESOZOIC		Glen Canyon Group:		
	Jurassic and Triassic (?)	Navajo Sandstone	300 - 400	Buff to light gray, massive, cross-bedded, friable sandstone
	Triassic (?)	Kayenta Formation	100 - 150	Reddish-brown sandstone and mudstone and occasional conglomerate lenses
	Triassic	Wingate Sandstone	250 - 350	Reddish-brown, massive, cross-bedded, fine-grained sandstone
		Chinle Formation:		
		Undivided	600 - 700	Variegated claystone with some thin beds of siltstone and limestone
		Moss Back Member	0 - 100	Light colored, conglomeratic sandstone and conglomerite
		Shinarump Member	0 - 20	Yellowish-gray, fine to coarse-grained sandstone: conglomeratic sandstone and conglomerate
		Unconformity		
	Middle (?) and Lower Triassic	Moenkopi Formation	50 - 100	Reddish-brown mudstone and fine-grained sandstone
		Unconformity		
PALEOZOIC	Permian	Cutler Formation:		
		Organ Rock Member	0 - 600	Reddish-brown, sandy mudstone
		Cedar Mesa Sandstone Member	1100 - 1400	Reddish-brown, massive, fine to medium-grained sandstone
	Pennsylvanian and Permian (?)	Rico Formation	450	Red and gray calcareous, sandy shale: gray limestone and sandstone
	Pennsylvanian	Hermosa Formation:		
		Upper Member	1000 - 1200	Gray, massive limestone: some shale and sandstone
		Paradox Member	1200	Halite, anhydrite, gypsum, shale, and siltstone
		Lower Member	200	Limestone, siltstone, and shale
		Unconformity		
	Mississippian	Leadville Limestone	500	White to tan sucrose to crystalline limestone
	Devonian	Ouray Limestone	100	Light gray and tan, thin-bedded limestone and dolomite
		Zilbert Formation	200	Gray and brown dolomite and limestone with thin beds green shale and sandstone
		Unconformity		
	Cambrian	Ophir Formation and Tintic Quartzite	600	Gray and brown limestone and dolomite, feldspathic sandstone and arkose

Table 1.6-2
Generalized Stratigraphic Section of Exposed Rocks in the Project Vicinity (Table 2.6-2 UMETCO)

ERA	SYSTEM	SERIES (Age)		STRATIGRAPHIC UNIT	THICKNESS* (ft.)	LITHOLOGY
CENOZOIC	QUATERNARY	Holocene to Pleistocene		Alluvium	2 - 25+	Silt, sand and gravel in arroyos and stream valleys.
CENOZOIC	QUATERNARY	Holocene to Pleistocene		Colluvium and Talus	0 - 15+	Slope wash, talus and rock rubble ranging from cobbles and boulders to massive blocks fallen from cliffs and outcrops of resistant rock.
CENOZOIC	QUATERNARY	Holocene to Pleistocene		Loess	0 - 22+	Reddish-brown to light-brown, unconsolidated, well-sorted silt to medium-grained sand; partially cemented with caliche in some area; reworked partly by water.
				Unconformity		
MESOZOIC	CRETACEOUS	Upper Cretaceous		Mancos Shale	0 - 11(?)	Gray to dark-gray, fissile, thin-bedded marine shale with fossiliferous sandy limestone in lower strata.
MESOZOIC	CRETACEOUS	Upper Cretaceous		Dakota Sandstone	30 - 75	Light yellowish-brown to light gray-brown, thick bedded to cross-bedded sandstone, conglomeratic sandstone; interbedded this lenticular gray carbonaceous claystone and impure coal; local course basal conglomerate.
				Unconformity		
MESOZOIC	CRETACEOUS	Lower Cretaceous		Burro Canyon Formation	50 - 150	Light-gray and light-brown, massive and cross-bedded conglomeratic sandstone and interbedded green and gray-green mudstone; locally contains thin discontinuous beds of silicified sandstone and limestone near top.
				Unconformity (?)		
MESOZOIC	Jurassic	Upper Jurassic	Morrison Formation	Brushy Basin Member	200 - 450	Variegated gray, pale-green, reddish-brown, and purple bentonitic mudstone and siltstone containing thin discontinuous sandstone and comglomerate lenses.
MESOZOIC	Jurassic	Upper Jurassic	Morrison Formation	Westwater Canyon Member	0 - 250	Interbedded yellowish- and greenish-gray to pinkish-gray, fine- to course-grained arkosic sandstone and greenish-gray to reddish-brown sandy shale and mudstone.
MESOZOIC	Jurassic	Upper Jurassic	Morrison Formation	Recapture Member	0 - 200	Interbedded reddish-gray to light brown fine-to medium-grained sandstone and reddish-gray silty and sandy claystone.
MESOZOIC	Jurassic	Upper Jurassic	Morrison Formation	Salt Wash Member	0 - 350	Interbedded yellowish-brown to pale reddish-brown fine-grained to conglomeritic sandstones and greenish- and reddish-gray mudstone.
				Unconformity		
MESOZOIC	Jurassic	Upper Jurassic	San Rafael Group	Bluff Sandstone	0 - 150+	White to grayish-brown, massive, cross-bedded, fine- to medium-grained eolian sandstone.
MESOZOIC	Jurassic	Upper Jurassic	San Rafael Group	Summerville Formation	25 - 125	Thin-bedded, ripple-marked reddish-brown muddy sandstone and sandy shale.
MESOZOIC	Jurassic	Upper Jurassic	San Rafael Group	Entrada Sandstone	150 - 180	Reddish-brown to grayish-white, massive, cross-bedded, fine- to medium-grained sandstone.
MESOZOIC	Jurassic	Middle Jurassic	San Rafael Group	Carmel Formation	20 - 100+	Irregularly bedded reddish-brown muddy sandstone and sandy mudstone with local thin beds of brown to gray limestone and reddish- to greenish-gray shale.
				Unconformity

Paleozoic rocks of Cambrian, Devonian and Mississippian ages are not exposed in the southeastern Utah region. Most of the geologic knowledge regarding these rocks was learned from the deeper oil wells drilled in the region, and from exposures in the Grand Canyon to the southwest and in the Uinta and Wasatch Mountains to the north. A few patches of Devonian rocks are exposed in the San Juan Mountains in southwestern Colorado. These Paleozoic rocks are the result of periodic transgressions and regressions of epicontinental seas and their lithologies reflect a variety of depositional environments.

In general, the coarse-grained feldspathic rocks overlying the Precambrian basement rocks grade upward into shales, limestones and dolomites that dominate the upper part of the Cambrian. Devonian and Mississippian dolomites, limestones and interbedded shales unconformably overlay the Cambrian strata. The complete absence of Ordovician and Silurian rocks in the Grand Canyon, Uinta Mountains, southwest Utah region and adjacent portions of Colorado, New Mexico and Arizona indicate that the region was probably epeirogenically positive during these times.

The oldest stratigraphic unit that crops out in the region is the Hermos formation of Middle and Late Pennsylvanian age. Only the uppermost strata of this formation are exposed, the best exposure being in the canyon of the San Juan River at the "Goosenecks" where the river traverses the crest of the Monument uplift. Other exposures are in the breached centers of the Lisbon Valley, Moab and Castle Valley anticlines. The Paradox Member of the Hermosa formation is sandwiched between a relatively thin lower unnamed member consisting of dark-gray shale siltstone, dolomite, anhydrite, and limestone, and an upper unnamed member of similar lithology but having a much greater thickness. Composition of the Paradox Member is dominantly a thick sequence of interbedded slate (halite), anhydrite, gypsum, and black shale. Surface exposures of the Paradox in the Moab and Castle Valley anticlines are limited to contorted residues of gypsum and black shale.

Conformably overlying the Hermosa is the Pennsylvanian and Permian (?) Rico formation, composed of interbedded reddish-brown arkosic sandstone and gray marine limestone. The Rico represents a transition zone between the predominantly marine Hermosa and the overlying continental Cutler formation of Permian age.

Two members of the Cutler probably underlying the region south of Blanding are, in ascending order, the Cedar Mesa Sandstone and the Organ Rock Tongue. The Cedar Mesa is a white to pale reddish-brown, massive, cross-bedded, fine- to medium-grained eolian sandstone. An irregular fluvial sequence of reddish-brown fine-grained sandstones, shaly siltstones and sandy shales comprise the Organ Rock Tongue.

The Moenkopi formation, of Middle (?) and Lower Triassic age, unconformably overlies the Cutler strata. It is composed of thin, evenly-bedded, reddish to chocolate-brown, ripple-marked, cross-laminated siltstone and sandy shales with irregular beds of massive medium-grained sandstone.

A thick sequence of complex continental sediments known as the Chinle formation unconformably overlies the Moenkopi. For the purpose of making lithology correlations in oil wells this formation is divided into three units: The basal Shinarump Member, the Moss Back Member and an upper undivided thick sequence of variegated reddish-brown, reddish- to greenish-gray, yellowish-brown to light-brown bentonitic claystones, mudstones, sandy siltstone, fine-grained sandstone, and limestones. The basal Shinarump is dominantly a yellowish-grey, fine- to coarse-grained sandstone, conglomeratic sandstone and conglomerate characteristically filling ancient stream channel scours eroded into the Moenkopi surface. Numerous uranium deposits have been located in this member in the White Canyon mining district to the west of Comb Ridge. The Moss Back is typically composed of yellowish- to greenish-grey, fine- to medium-grained sandstone, conglomeratic sandstone and conglomerate. It commonly comprises the basal unit of the Chinle where the Shinarump was not deposited, and in a like manner, fills ancient stream channels scoured into the underlying unit.

In the Blanding Basin the Glen Canyon Group consists of three formations which are, in ascending order, the Wingate Sandstone, the Kayenta and the Navajo Sandstone. All are conformable and their contacts are gradational. Commonly cropping out in sheer cliffs, the Late Triassic Wingate Sandstone is typically composed of buff to reddish-brown, massive, cross-bedded, well-sorted, fine-grained quartzose sandstone of eolian origin. Late Triassic (?) Kayenta is fluvial in origin and consists of reddish-brown, irregularly to cross-bedded sandstone, shaly sandstone and, locally, thin beds of limestone and conglomerate. Light yellowish-brown to light-gray and white, massive, cross-bedded, friable, fine- to medium-grained quartzose sandstone typifies the predominantly eolian Jurassic and Triassic (?) Navajo Sandstone.

Four formations of the Middle to Late Jurassic San Rafael Group unconformably overly the Navajo Sandstone. These strata are composed of alternating marine and non-marine sandstones, shales and mudstones. In ascending order, the formations are the Carmel formation, Entrada Sandstone, Summerville formation, and Bluff Sandstone. The Carmel usually crops out as a bench between the Navajo and Entrada Sandstones. Typically reddish-brown muddy sandstone and sandy mudstone, the Carmel locally contains thin beds of brown to gray limestone and reddish- to greenish-gray shale. Predominantly eolian in origin, the Entrada is a massive cross-bedded fine- to medium-grained sandstone ranging in color from reddish-brown to grayish-white that crops out in cliffs or hummocky slopes. The Summerville is composed of regular thin-bedded, ripple-marked, reddish-brown muddy sandstone and sandy shale of marine origin and forms steep to gentle slopes above the Entrada. Cliff-forming Bluff Sandstone is present only in the southern part of the Monticello district thinning northward and pinching out near Blanding. It is a white to grayish-brown, massive, cross-bedded eolian sandstone.

In the southeastern Utah region the Late Jurassic Morrison formation has been divided in ascending order into the Salt Wash, Recapture, Westwater Canyon, and Brushy Basin Members. In general, these strata are dominantly fluvial in origin but do contain lacustrine sediments. Both the Salt Wash and Recapture consist of alternating mudstone and sandstone; the Westwater Canyon is chiefly sandstone with some sandy mudstone and claystone lenses, and the heterogenous Brushy Basin consists of variegated bentonitic mudstone and siltstone containing scattered thin limestone, sandstone, and conglomerate lenses. As strata of the Morrison formation are the oldest rocks exposed in the Mill area vicinity and are one of the two principal uranium-bearing formations in southeast Utah, the Morrison, as well as younger rocks, are described in more detail in Section 1.6.2.2.

The Early Cretaceous Burro Canyon formation rests unconformably (?) on the underlying Brushy Basin Member of the Morrison formation. Most of the Burro Canyon consists of light-colored, massive, cross-bedded fluvial conglomerate, conglomerate sandstone and sandstone. Most of the conglomerates are near the base. Thin, even-bedded, light-green mudstones are included in the formation and light-grey thin-bedded limestones are sometimes locally interbedded with the mudstones near the top of the formation.

Overlying the Burro Canyon is the Dakota Sandstone of Upper Cretaceous age. Typical Dakota is dominantly yellowish-brown to light-gray, thick-bedded, quartzitic sandstone and conglomeratic sandstone with subordinate thin lenticular beds of mudstone, gray carbonaceous shale and, locally, thin seams of impure coal. The contact with the underlying Burro Canyon is unconformable whereas the contact with the overlying Mancos Shale is gradational from the light-colored sandstones to dark-grey to black shaly siltstone and shale.

Upper Cretaceous Mancos Shale is exposed in the region surrounding the project vicinity but not within it. Where exposed and weathered, the shale is light-gray or yellowish-gray, but is dark, to olive-gray where fresh. Bedding is thin and well developed; much of it is laminated.

Quaternary alluvium within the project vicinity is of three types: alluvial silt, sand and gravels deposited in the stream channels; colluvium deposits of slope wash, talus, rock rubble and large displaced blocks on slopes below cliff faces and outcrops of resistant rock; and alluvial and windblown deposits of silt and sand, partially reworked by water, on benches and broad upland surfaces.

1.6.1.3 Structure and Tectonics (1978 ER Section 2.4.1.3)

According to Shoemaker (1954 and 1956), structural features within the Canyon Lands of southeastern Utah may be classified into three main categories on the basis of origin or mechanism of the stress that created the structure. These three categories are: (1) structures related to large-scale regional uplifting or downwarping (epeirogenic deformation) directly related to movements in the basement complex (Monument Uplift and the Blanding Basin); (2) structures resulting from the plastic deformation of thick sequences of evaporite deposits, salt plugs and salt anticlines, where the structural expression at the surface is not reflected in the basement complex (Paradox Fold and Fault Belt); and (3) structures that are formed in direct response to stresses induced by magmatic intrusion including local laccolithic domes, dikes and stocks (Abajo Mountains).

Each of the basins and uplifts within the Mill area region is an asymmetric fold usually separated by a steeply dipping sinuous monocline. Dips of the sedimentary beds in the basins and uplifts rarely exceed a few degrees except along the monocline (Shoemaker, 1956) where, in some instances, the beds are nearly vertical. Along the Comb Ridge monocline, the boundary between the Monument Uplift and the Blanding Basin, approximately eight miles (12.9 kilometers) west of the Mill area, dips in the Upper Triassic Wingate sandstone and in the Chinle formation are more than 40 degrees to the east.

Structures in the crystalline basement complex in the central Colorado Plateau are relatively unknown but where monoclines can be followed in Precambrian rocks they pass into steeply dipping faults. It is probable that the large monoclines in the Canyon Lands section are related to flexure of the layered sedimentary rocks under tangential compression over nearly vertical normal or high-angle reverse faults in the more rigid Precambrian basement rocks (Kelley, 1955; Shoemaker, 1956; Johnson and Thordarson, 1966).

The Monument Uplift is a north-trending, elongated, upwarped structure approximately 90 miles (145 kilometers) long and nearly 35 miles (56 kilometers) wide. Structural relief is about 3,000 feet (914 meters) (Kelley, 1955). Its broad crest is slightly convex to the east where the Comb Ridge monocline defines the eastern boundary. The uniform and gently descending western flank of the uplift crosses the White Canyon slope and merges into the Henry Basin (Figure 1.6-1).

East of the Monument Uplift, the relatively equidimensional Blanding Basin merges almost imperceptibly with the Paradox Fold and Fault Belt to the north, the Four Corners Platform to the southeast and the Defiance Uplift to the south. The basin is a shallow feature with approximately 700 feet (213 meters) of structural relief as estimated on top of the Upper Triassic Chinle formation by Kelley (1955), and is roughly 40 to 50 miles (64 to 80 kilometers) across. Gentle folds within the basin trend westerly to northwesterly in contrast to the distinct northerly orientation of the Monument Uplift.

Situated to the north of the Monument Uplift and Blanding Basin is the most unique structural feature of the Canyon Lands section, the Paradox Fold and Fault Belt. This tectonic unit is dominated by northwest trending anticlinal folds and associated normal faults covering an area about 150 miles (241 kilometers) long and 65 miles (104 kilometers) wide. These anticlinal structures are associated with salt flowage from the Pennsylvanian Paradox Member of the Hermosa formation and some show piercement of the overlying younger sedimentary beds by plug-like salt intrusions (Johnson and Thordarson, 1966). Prominent valleys have been eroded along the crests of the anticlines where salt piercements have occurred or collapses of the central parts have resulted in intricate systems of step-faults and grabens along the anticlinal crests and flanks.

The Abajo Mountains are located approximately 20 miles (32 kilometers) north of the Mill area on the more-or-less arbitrary border of the Blanding Basin and the Paradox Fold and Fault Belt (Figure 1.6-1). These mountains are laccolithic domes that have been intruded into and through the sedimentary rocks by several stocks (Witkind, 1964). At least 31 laccoliths have been identified. The youngest sedimentary rocks that have been intruded are those of Mancos Shale of Late Cretaceous age. Based on this and other vague and inconclusive evidence, Witkind (1964), has assigned the age of these intrusions to the Late Cretaceous or early Eocene.

Nearly all known faults in the region of the Mill area are high-angle normal faults with displacements on the order of 300 feet (91 meters) or less (Johnson and Thordarson, 1966). The largest known faults within a 40-mile (64 kilometer) radius around Blanding are associated with the Shay graben on the north side of the Abajo Mountains and the Verdure graben on the south side. Respectively, these faults trend northeasterly and easterly and can be traced for approximate distances ranging from 21 to 34 miles (34 to 55 kilometers) according to Witkind (1964). Maximum displacements reported by Witkind on any of the faults are 320 feet (98 meters). Because of the extensions of Shay and Verdure fault systems beyond the Abajo Mountains and other geologic evidence, the age of these faults is Late Cretaceous or post-Cretaceous and antedate the laccolithic intrusions (Witkind, 1964).

A prominent group of faults is associated with the salt anticlines in the Paradox Fold and Fault Belt. These faults trend northwesterly parallel to the anticlines and are related to the salt emplacement. Quite likely, these faults are relief features due to salt intrusion or salt removal by solution (Thompson, 1967). Two faults in this region, the Lisbon Valley fault associated with the Lisbon Valley salt anticline and the Moab fault at the southeast end of the Moab anticline have maximum vertical displacements of at least 5,000 feet (1,524 meters) and 2,000 feet (609 meters), respectively, and are probably associated with breaks in the Precambrian basement crystalline complex. It is possible that zones of weakness in the basement rocks represented by faults of this magnitude may be responsible for the beginning of salt flowage in the salt anticlines, and subsequent solution and removal of the salt by groundwater caused collapse within the salt anticlines resulting in the formation of grabens and local complex block faults (Johnson and Thordarson, 1966).

The longest faults in the Colorado Plateau are located some 155 to 210 miles (249 to 338 kilometers) west of the Mill area along the western margin of the High Plateau section. These faults have a north to northeast echelon trend, are nearly vertical and downthrown on the west in most places. Major faults included in this group are the Hurricane, Toroweap-Sevier, Paunsaugunt, and Paradise faults. The longest fault, the Toroweap-Sevier, can be traced for about 240 miles (386 kilometers) and may have as much as 3,000 feet (914 meters) of displacement (Kelley, 1955).

From the later part of the Precambrian until the middle Paleozoic the Colorado Plateau was a relatively stable tectonic unit undergoing gentle epeirogenic uplifting and downwarping during which seas transgressed and regressed, depositing and then partially removing layers of sedimentary materials. This period of stability was interrupted by northeast-southwest tangential compression that began sometime during late Mississippian or early Pennsylvanian and continued intermittently into the Triassic. Buckling along the northeast margins of the shelf produced northwest-trending uplifts, the most prominent of which are the Uncompahgre and San Juan Uplifts, sometimes referred to as the Ancestral Rocky Mountains. Clearly, these positive features are the earliest marked tectonic controls that may have guided many of the later Laramide structures (Kelley, 1955).

Subsidence of the area southwest of the Uncompahgre Uplift throughout most of the Pennsylvanian led to the filling of the newly formed basin with an extremely thick sequence of evaporites and associated interbeds which comprise the Paradox Member of the Hermosa formation (Kelley, 1958). Following Paradox deposition, continental and marine sediments buried the evaporite sequence as epeirogenic movements shifted shallow seas across the region during the Jurassic, Triassic and much of the Cretaceous. The area underlain by the Paradox Member in eastern Utah and western Colorado is commonly referred to as the Paradox Basin (Figure 1.6-1). Renewed compression during the Permian initiated the salt anticlines and piercements, and salt flowage continued through the Triassic.

The Laramide orogeny, lasting from Late Cretaceous through Eocene time, consisted of deep-seated compressional and local vertical stresses. The orogeny is responsible for a north-south to northwest trend in the tectonic fabric of the region and created most of the principal basins and uplifts in the eastern-half of the Colorado Plateau (Grose, 1972; Kelley, 1955).

Post-Laramide epeirogenic deformation has occurred throughout the Tertiary; Eocene strata are flexed sharply in the Grand Hogback monocline, fine-grained Pliocene deposits are tilted on the flanks of the Defiance Uplift, and Pleistocene deposits in Fisher Valley contain three angular unconformaties (Shoemaker, 1956).

1.6.2 Blanding Site Geology

The following descriptions of physiography and topography; rock units; structure; relationship of earthquakes to tectonic structure; and potential earthquake hazards to the Mill area are reproduced from the 1978 ER for ease of reference and as a review of the Mill site geology (see Figure 1.6-2).

1.6.2.1 Physiography and Topography (1978 ER Section 2.4.2.1)

The Mill site is located near the center of White Mesa, one of the many finger-like north-south trending mesas that make up the Great Sage Plain. The nearly flat upland surface of White Mesa is underlain by resistant sandstone caprock which forms steep prominent cliffs separating the upland from deeply entrenched intermittent stream courses on the east, south and west.

Surface elevations across the Mill site range from about 5,550 to 5,650 feet (1,692 to 1,722 meters) and the gently rolling surface slopes to the south at a rate of approximately 60 feet per mile (18 meters per 1.6 kilometer).

FIGURE 1.6-2

WHITE MESA MILLSITE
GEOLOGY OF SURROUNDING AREA

Date: Nov. 2009 Design: Drafted By: RAH

Maximum relief between the mesa's surface and Cottonwood Canyon on the west is about 750 feet (229 meters) where Westwater Creek joins Cottonwood Wash. These two streams and their tributaries drain the west and south sides of White Mesa. Drainage on the east is provided by Recapture Creek and its tributaries. Both Cottonwood Wash and Recapture Creeks are normally intermittent streams and flow south to the San Juan River. However, Cottonwood Wash has been known to flow perennially in the project vicinity during wet years.

1.6.2.2 Rock Units (1978 ER Section 2.4.2.2)

Only rocks of Jurassic and Cretaceous ages are exposed in the vicinity of the Mill site. These include, in ascending order, the Upper Jurassic Salt Wash, Recapture, Westwater Canyon, and Brushy Basin Members of the Morrison formation; the Lower Cretaceous Burro Canyon formation; and the Upper Cretaceous Dakota Sandstone. The Upper Cretaceous Mancos Shale is exposed as isolated remnants along the rim of Recapture Creek valley several miles southeast of the Mill site and on the eastern flanks of the Abajo Mountains some 20 miles (32 kilometers) north but is not exposed at the Mill site. However, patches of Mancos Shale may be present within the Mill site boundaries as isolated buried remnants that are obscured by a mantle of alluvial windblown silt and sand.

The Morrison formation is of particular economic importance in southeast Utah since several hundred uranium deposits have been discovered in the basal Salt Wash Member (Stokes, 1967).

In most of eastern Utah, the Salt Wash Member underlies the Brushy Basin. However, just south of Blanding in the project vicinity the Recapture Member replaces an upper portion of the Salt Wash and the Westwater Canyon Member replaces a lower part of the Brushy Basin. A southern limit of Salt Wash deposition and a northern limit of Westwater Canyon deposition has been recognized by Haynes et al. (1972) in Westwater Canyon approximately three to six miles (4.8 to 9.7 kilometers), respectively, northwest of the Mill site. However, good exposures of Salt Wash are found throughout the Montezuma Canyon area 13 miles (21 kilometers) to the east.

The Salt Wash Member is composed dominantly of fluvial fine-grained to conglomeratic sandstones, and interbedded mudstones. Sandstone intervals are usually yellowish-brown to pale reddish-brown while the mudstones are greenish- and reddish-gray. Carbonaceous materials ("trash") vary from sparse to abundant. Cliff-forming massive sandstone and conglomeratic sandstone in discontinuous beds make up to 50 percent or more of the member. According to Craig et al. (1955), the Salt Wash was deposited by a system of braided streams flowing generally east and northeast. Most of the uranium-vanadium deposits are located in the basal sandstones and conglomeratic sandstones that fill stream-cut scour channels in the underlying Bluff Sandstone, or where the Bluff Sandstone has been removed by pre-Morrison erosion, in similar channels cut in the Summerville formation. Mapped thicknesses of this member range from zero to approximately 350 feet (0-107 meters) in southeast Utah. Because the Salt Wash pinches out in a southerly direction in Recapture Creek three miles (4.8 kilometers) northwest of the Mill site and does not reappear until exposed in Montezuma Canyon, it is not known for certain that the Salt Wash actually underlies the site.

The Recapture Member is typically composed of interbedded reddish-gray, white, and light-brown fine- to medium-grained sandstone and reddish-gray, silty and sandy claystone. Bedding is gently to sharply lenticular. Just north of the Mill site, the Recapture intertongues with and grades into the Salt Wash and the contact between the two cannot be easily recognized. A few spotty occurrences of uriniferous mineralization are found in sandstone lenses in the southern part of the Monticello district and larger deposits are known in a conglomeratic sandstone facies some 75 to 100 miles (121 to 161 kilometers) southeast of the Monticello district. Since significant ore deposits have not been found in extensive outcrops in more favorable areas, the Recapture is believed not to contain potential resources in the Mill site (Johnson and Thordarson, 1966).

Just north of the Mill site, the Westwater Canyon Member intertongues with and grades into the lower part of the overlying Brushy Basin Member. Exposures of the Westwater Canyon in Cottonwood Wash are typically composed of interbedded yellowish- and greenish-gray to pinkish-gray, lenticular, fine- to coarse-grained arkosic sandstone and minor amounts of greenish-gray to reddish-brown sandy shale and mudstone. Like the Salt Wash, the Westwater Canyon Member is fluvial in origin, having been deposited by streams flowing north and northwest, coalescing with streams from the southwest depositing the upper part of the Salt Wash and the lower part of the Brushy Basin (Huff and Lesure, 1965). Several small and scattered uranium deposits in the Westwater Canyon are located in the extreme southern end of the Monticello district. Both the Recapture Member and the Westwater Canyon contain only traces of carbonaceous materials, are believed to be less favorable host rocks for uranium deposition (Johnson and Thordarson, 1966) and have very little potential for producing uranium reserves.

The lower part of the Brushy Basin is replaced by the Westwater Canyon Member in the Blanding area but the upper part of the Brushy Basin overlies this member. Composition of the Brushy Basin is dominantly variegated bentonitic mudstone and siltstone. Bedding is thin and regular and usually distinguished by color variations of gray, pale-green, reddish-brown, pale purple, and maroon. Scattered lenticular thin beds of distinctive green and red chert-pebble conglomeratic sandstone are found near the base of the member, some of which contain uranium-vanadium mineralization in the southernmost part of the Monticello district (Haynes et al., 1972). Thin discontinuous beds of limestone and beds of grayish-red to greenish-black siltstone of local extent suggest that much of the Brushy Basin is probably lacustrine in origin.

For the most part, the Great Sage Plain owes its existence to the erosion of resistant sandstones and conglomerates of the Lower Cretaceous Burro Canyon formation. This formation unconformably (?) overlies the Brushy Basin and the contact is concealed over most of the Mill area by talus blocks and slope wash. Massive, light-gray to light yellowish-brown sandstone, conglomeratic sandstone and conglomerate comprise more than two-thirds of the formation's thickness. The conglomerate and sandstone are interbedded and usually grade from one to the other. However, most of the conglomerate is near the base. These rocks are massive cross-bedded units formed by a series of interbedded lenses, each lens representing a scour filled with stream-deposited sediments. In places the formation contains greenish-gray lenticular beds of mudstone and claystone. Most of the Burro Canyon is exposed in the vertical cliffs separating the relatively flat surface of White Mesa from the canyons to the west and east. In some places the resistant basal sandstone beds of the overlying Dakota Sandstone are exposed at the top of the cliffs, but entire cliffs of Burro Canyon are most common. Where the sandstones of the Dakota rest on sandstones and conglomerates of the Burro Canyon, the contact between the two is very difficult to identify and most investigators map the two formations as a single unit (Figure 1.6-2). At best, the contact can be defined as the top of a silicified zone in the upper part of the Burro Canyon that appears to be remnants of an ancient soil that formed during a long period of weathering prior to Dakota deposition (Huff and Lesure, 1965).

The Upper Cretaceous Dakota Sandstone disconformably overlies the Burro Canyon formation. Locally, the disconformity is marked by shallow depressions in the top of the Burro Canyon filled with Dakota sediments containing angular to sub-rounded rock fragments probably derived from Burro Canyon strata (Witkind, 1964) but the contact is concealed at the Mill site. The Dakota is composed predominantly of pale yellowish-brown to light gray, massive, intricately cross-bedded, fine- to coarse-grained quartzose sandstone locally well-cemented with silica and calcite; elsewhere it is weakly cemented and friable. Scattered throughout the sandstone are lenses of conglomerate, dark-gray carbonaceous mudstones and shale and, in some instances, impure coal. In general, the lower part of the Dakota is more conglomeratic and contains more cross-bedded sandstone than the upper part which in normally more thinly bedded and marine-like in appearance. The basal sandstones and conglomerates are fluvial in origin, whereas the carbonaceous mudstones and shales were probably deposited in back water areas behind beach ridges in front of the advancing Late Cretaceous sea (Huff and Lesure, 1965). The upper sandstones probably represent littoral marine deposits since they grade upward into the dark-gray siltstones and marine shales of the Mancos Shale.

The Mancos shale is not exposed in the project vicinity. The nearest exposures are small isolated remnants resting conformably on Dakota Sandstone along the western rim above Recapture Creek 4.3 to 5.5 miles (6.9 to 8.9 kilometers) southeast of the Mill site. Additional exposures are found on the eastern and southern flanks of the Abajo Mountains approximately 16 to 20 miles (26 to 32 kilometers) to the north. It is possible that thin patches of Mancos may be buried at the Mill site but are obscured by the mantle of alluvial windblown silt and sand covering the upland surface. The Upper Cretaceous Mancos shale is of marine origin and consists of dark- to olive-gray shale with minor amounts of gray, fine-grained, thin-bedded to blocky limestone and siltstone in the lower part of the formation. Bedding in the Mancos is thin and well developed, and much of the shale is laminated. Where fresh, the shale is brittle and fissile and weathers to chips that are light- to yellowish-gray. Topographic features formed by the Mancos are usually subdued and commonly displayed by low rounded hills and gentle slopes.

A layer of Quaternary to Recent reddish-brown eolian silt and fine sand is spread over the surface of the Mill site. Most of the loess consists of subangular to rounded frosted quartz grains that are coated with iron oxide. Basically, the loess is massive and homogeneous, ranges in thickness from a dust coating on the rocks that form the rim cliffs to more than 20 feet (6 meters), and is partially cemented with calcium carbonate (caliche) in light-colored mottled and veined accumulations which probably represent ancient immature soil horizons.

1.6.2.3 Structure (1978 ER Section 2.4.2.3)

The geologic structure at the Mill site is comparatively simple. Strata of the underlying Mesozoic sedimentary rocks are nearly horizontal; only slight undulations along the caprock rims of the upland are perceptible and faulting is absent. In much of the area surrounding the Mill site the dips are less than one degree. The prevailing regional dip is about one degree to the south. The low dips and simple structure are in sharp contrast to the pronounced structural features of the Comb Ridge Monocline to the west and the Abajo Mountains to the north.

The Mill area is within a relatively tectonically stable portion of the Colorado Plateau noted for its scarcity of historical seismic events. The epicenters of historical earthquakes from 1853 through 1986 within a 200-mile (320 km) radius of the site are shown in Figure 1.6-3. More than 1,146 events have occurred in the area, of which at least 45 were damaging; that is, having an intensity of VI or greater on the Modified Mercalli Scale. A description of the Modified Mercalli Scale is given in Table 1.6-3. All intensities mentioned herein refer to this table. Table 1.6-3 also shows a generalized relationship between Mercalli intensities and other parameters to which this review will refer. Since these relationships are frequently site specific, the table values should be used only for approximation and understanding. Conversely, the border between the Colorado Plateau and the Basin and Range Province and Middle Rocky Mountain

Table 1.6-3 Modified Mercalli Scale

Modified Mercalli Scale, 1956 Version[a]				
	Intensity	Effects	v. † cm/s	g ‡
M§	I.	Not felt. Marginal and long-period effects of large earthquakes (for details see text).		
3	II.	Felt by persons at rest on upper floors, or favorably placed.		
	III.	Felt indoors. Hanging objects swing. Vibration like passing of light trucks. Duration estimated. May not be recognized as an earthquake.		0.0035-0.007
4	IV.	Hanging objects swing. Vibration like passing of heavy trucks or sensation of a jolt like a heavy ball striking the walls. Standing motor cars rock. Windows, dishes, doors rattle. Glasses clink. Crockery clashes. In the upper range of IV wooden walls and frame creak.		0.007-0.015
	V.	Felt outdoors: direction estimated. Sleepers wakened. Liquids disturbed. Some spilled. Small unstable objects displaced or upset. Doors swing close, open. Shutters, pictures move. Pendulum clocks stop, start, change rate.	1-3	0.015-0.035
5	VI.	Felt by all. Many frightened and run outdoors. Persons walk unsteadily. Windows, dishes, glassware broken. Knickknacks, books, etc. off shelves. Pictures off walls. Furniture moved or overturned. Weak plaster and masonry D cracked. Small bells ring (church, school). Trees, bushes shaken (visibly, or heard to rustle - CFR).	3-7	0.035-0.07
6	VII.	Difficult to stand. Noticed by drivers of motor cars. Hanging objects quiver. Furniture broken. Damage to masonry D including cracks. Weak chimneys broken at roof line. Fall of plaster, loose bricks, stones, tiles, cornices (also unbraced parapets and architectural ornaments - CFR). Some cracks in masonry C. Waves on ponds: water turbid with mud. Small slides and caving in along sand or gravel banks. Large bells ring. Concrete irrigation ditches damaged.	7-20	0.07-0.15
	VIII.	Steering of motor cars affected. Damage to masonry C; partial collapse. Some damage to masonry B; none is masonry A. Fall of stucco and some masonry walls. Twisting, fall of chimneys, factory stacks, monuments, towers, elevated tanks. Frame houses moved on foundations if not bolted down; loose panel walls thrown out. Decayed piling broken off. Branches broken from trees. Changes in flow or temperature of springs and wells. Cracks in wet ground and on steep slopes.	20-80	0.15-0.35
7	IX.	General panic. Masonry D destroyed, masonry C heavily damaged. Sometimes with complete collapse, masonry B seriously damaged. (General damage to foundations - CFR). Frame structures, if not bolted, shifted off foundations. Frames rocked. Serious damage to reservoirs. Underground pipes broken. Conspicuous cracks in ground. In alluviated areas sand and mud ejected, earthquake fountains, sand craters.	.80-200	0.35-0.7
8	X.	Most masonry and frame structures destroyed with their foundations. Some well-built wooden structures and bridges destroyed. Serious damage to dams, dikes, embankments. Large landslides. Water thrown on banks of canals, rivers, lakes, etc. Sand and mud shifted horizontally on beaches and flat land. Rails bent slightly.	200-500	0.7-1.2
	XI.	Rails bent greatly. Underground pipelines completely out of service.		>1.2
	XII.	Damage nearly total. Large rock masses displaced. Lines of sight and level distorted. Objects thrown into the air.	From Fig. 11.14	

Note: Masonry A, B, C, D. To avoid ambiguity of language, the quality of masonry, brick or otherwise, is specified by the following lettering (which has no connection with the conventional Class A, B, C construction).

- Masonry A : Good workmanship, mortar, and design reinforced, especially laterally, and bound together by using steel, concrete, etc.; designed to resist lateral forces.
- Masonry B: Good workmanship and mortar; reinforced, but not designed to resist lateral forces.
- Masonry C: Ordinary workmanship and mortar; no extreme weaknesses such as non-ded-ia corners, but masonry is neither reinforced nor designed against horizontal forces.
- Masonry D : Week materials such as adobe, poor mortar, low standards of workmanship, week horizontally.

§Magnitude correlation.

Province some 155 to 240 miles (249 to 386 km) west and northwest, respectively, from the site is one of the most active seismic belts in the western United States.

Only 63 non-duplicative epicenters have been recorded within a 120 mile (200 km) radius of the Mill area (Figure 1.6-4). Of these, 50 had an intensity IV or less (or unrecorded) and two were recorded as intensity VI. The nearest event occurred in the Glen Canyon National Recreation Area approximately 38 miles (63 km) west-northwest of the Mill area. The next closest event occurred approximately 53 miles (88 km) to the northeast. Just east of Durango, Colorado, approximately 99 miles (159 km) due east of the Mill area, an event having local intensity of V was recorded on August 29, 1941 (Hadsell, 1968). It is very doubtful that these events would have been felt in the vicinity of Blanding.

Three of the most damaging earthquakes associated with the seismic belt along the Colorado Plateau's western border have occurred in the Elsinore-Richfield are about 168 miles (270 km) northwest of the Mill site. All were of intensity VIII. On November 13, 1901, a strong shock caused extensive damage from Richfield to Parowan. Many brick structures were damaged; rockslides were reported near Beaver. Earthquakes with the ejection of sand and water were reported, and some creeks increased their flow. Aftershocks continued for several weeks (von Hake, 1977). Following several weeks of small foreshocks, a strong earthquake caused major damage in the Monroe-Elsinore-Richfield area on September 29, 1921. Scores of chimneys were thrown down, plaster fell from ceilings, and a section of a new two-story brick wall collapsed at Elsinore's schoolhouse. Two days later, on October 1, 1921, another strong tremor caused additional damage to the area's structures. Large rockfalls occurred along both sides of the Sevier Valley and hot springs were discolored by iron oxides (von Hake, 1977). It is probable that these shocks may have been perceptible at the Mill site but they certainly would not have caused any damage.

Seven events of intensity VII have been reported within 320 kilometers (km) around Blanding, Utah, which is the area shown in Figure 1.6-3. Of these, only two are considered to have any significance with respect to the Mill site. On August 18, 1912, an intensity VII shock damaged houses in northern Arizona and was felt in Gallup, New Mexico, and southern Utah. Rock slides occurred near the epicenter in the San Francisco Mountains and a 50-mile (80 km) earth crack was reported north of the San Francisco Range (Cater, 1970). Nearly every building in Dulce, New Mexico, was damaged to some degree when shook by a strong earthquake on January 22, 1966. Rockfalls and landslides occurred 10 to 15 miles (16 to 24 km) west of Dulce along Highway 17 where cracks in the pavement were reported (Hermann et al., 1980). Both of these events may have been felt at the Mill site but, again, would certainly not have caused any damage. Figure 1.6-4 shows the occurrence of seismic events within 200 km of Blanding.

1.6.2.4 Relationship of Earthquakes to Tectonic Structures

The majority of recorded earthquakes in Utah have occurred along an active belt of seismicity that extends from the Gulf of California, through western Arizona, central Utah, and northward into western British Columbia. The seismic belt is possibly a branch of the active rift system associated with the landward extension of the East Pacific Rise (Cook and Smith, 1967). This belt is the Intermountain Seismic Belt shown in Figure 1.6-5 (Smith, 1978).

It is significant to note that the seismic belt forms the boundary zone between the Basin and Range - Great Basin Provinces and the Colorado Plateau - Middle Rocky Mountain Provinces. This block-faulted zone is about 47 to 62 miles (75 to 100 km) wide and forms a tectonic transition zone between the relatively simple structures of the Colorado Plateau and the complex fault-controlled structures of the Basin and Range Province (Cook and Smith, 1967).

Another zone of seismic activity is in the vicinity of Dulce, New Mexico, near the Colorado border. This zone, which coincides with an extensive series of tertiary intrusives, may also be related to the northern end of the Rio Grande Rift. This rift is a series of fault-controlled structural depressions extending southward from southern Colorado through central New Mexico and into Mexico. The rift is shown on Figure 1.6-5 trending north-south to the east of the Mill area.

Most of the events south of the Utah border of intensity V and greater are located within 50 miles (80 km) of post-Oligocene extrusives. This relationship is not surprising because it has been observed in many other parts of the world (Hadsell, 1968).

In Colorado, the Rio Grande Rift zone is one of three siesmotectonic provinces that may contribute energy to the study area. Prominent physiographic expression of the rift includes the San Luis Valley in southern Colorado. The valley is a half-graben structure with major faulting on the eastern flank. Extensional tectonics is dominant in the area and very large earthquakes with recurrence intervals of several thousand years have been projected (Kirkham and Rogers, 1981). Mountainous areas to the west of the Rio Grande rift province include the San Juan Mountains. These mountains are a complex domicia uplift with extensive Oligocene and Miocene volcanic cover. Many faults are associated with the collapse of the calderas and apparently have not moved since. Faults of Neogene age exist in the eastern San Juan Mountains that may be related to the extension of the Rio Grande rift. Numerous small earthquakes have been felt or recorded in the western mountainous province despite an absence of major Neogene tectonic faults (Kirkham and Rogers, 1981).

The third seismotectonic province in Colorado, that of the Colorado Plateau, extends into the surrounding states to the west and south. In Colorado, the major tectonic element that has been recurrently active in the Quaternary is the Uncompahgre uplift. Both flanks are faulted and earthquakes have been felt in the area. The faults associated with the Salt Anticlines are collapsed features produced by evaporite solution and flowage (Cater, 1970). Their non-tectonic origin and the plastic deformation of the salt reduce their potential for generating even moderate-sized earthquakes (Kirkham and Rogers, 1981).

Case and Joesting (1972) have called attention to the fact that regional seismicity of the Colorado Plateau includes a component added by basement faulting. They inferred a basement fault trending northeast along the axis of the Colorado River through Canyonlands. This basement faulting may be part of the much larger structure that Hite (1975) examined and Warner (1978) named the Colorado lineament (Figure 1.6-6). This 1,300-mile (2,100 km) long lineament that extends from northern Arizona to Minnesota is suggested to be a Precambrian wrench-fault system formed some 2.0 to 1.7 billion years before present. While it has been suggested that the Colorado lineament is a source zone for larger earthquakes (m = 4 to 6) in the west-central United States, the observed spatial relationship between epicenters and the trace of the lineament does not prove a casual relation (Brill and Nuttli, 1983). In terms of contemporary seismicity, the lineament does not act as a uniform earthquake generator. Only specific portions of the proposed structure can presently be considered seismic source zones and each segment exhibits seismicity of distinctive activity and character (Wong, 1981). This is a reflection of the different orientations and magnitudes of the stress fields along the lineament. The interior of the Colorado Plateau forms a tectonic stress province, as defined by Zoback and Zoback (1980), that is characterized by generally east-west tectonic compression. Only where extensional stresses from the Basin and Range province of the Rio Grande rift extend into the Colorado Plateau would the Colorado lineament in the local area be suspected of having the capability of generating a large magnitude earthquake (Wong, 1984). At present, the well-defined surface expression of regional extension is far to the west and far to the east of the Mill area.

Work by Wong (1984) has helped define the seismicity of the whole Colorado Plateau. He called attention to the low level (less than local magnitude, ML = 3.6) but high number (30) of earthquakes in the Capitol Reef Area from 1978 to 1980 that were associated with the Waterpocket fold and the Cainville monocline, two other major tectonic features of the Colorado Plateau. Only five earthquakes in the sequence were of ML greater than three, and fault plane solutions suggest the swarm was produced by normal faulting along northwest-trending Precambrian basement structures (Wong, 1984). The significance of the Capitol Reef seismicity is its relatively isolated occurrence within the Colorado Plateau and its location at a geometric barrier in the regional stress field (Aki, 1979). Stress concentration that produces earthquakes at bends or junctures of basement faults as indicated by this swarm may occur at other locations in the Colorado Plateau Province. No inference that earthquakes such as those at Capitol Reef are precursors for larger subsequent events is implied.

1.6.2.5 Potential Earthquake Hazards to Mill Area

The Mill site is located in a region known for its scarcity of recorded seismic events. Although the seismic history for this region is barely 135 years old, the epicentral pattern, or fabric, is basically set and appreciable changes are not expected to occur. Most of the larger seismic events in the Colorado Plateau occurred along its margins rather than in the interior central region. Based on the region's seismic history, the probability of a major damaging earthquake occurring at or near the Mill site is remote. Studies by Algermissen and Perkins (1976) indicate that southeastern Utah, including the site, is in an area with a 90 percent probability that a horizontal acceleration of four percent gravity (0.04g) would not be exceeded within 50 years. In 2002, the USGS updated the National Seismic Hazard Maps (NSHM), which show peak ground and spectral accelerations at 2 percent and 10 percent probability of exceedance in 50 years. From these maps, it is determined that there is a 98 percent probability that a horizontal acceleration of 0.09g would not be exceeded within 50 years (Tetra Tech, 2006). Furthermore, an updated seismic hazard analysis performed by Tetra Tech (2010) for the site determined that there is a 98 percent probability that a horizontal acceleration of 0.15g would not be exceeded within a 200-year design life of the tailings management cells. The Tetra Tech (2010) report is included in Appendix D.

1.6.3 Site-Specific Probabilistic Seismic Hazard Analysis

A site-specific probabilistic seismic hazard analysis (PSHA) (MWH, 2015a) was conducted for the White Mesa Mill site. The PSHA was performed to better understand the likelihood of potential earthquake sources, to correlate results with previous analyses conducted for the site, and to evaluate the contribution of the seismic sources (e.g. deaggregation). This analysis assessed the site-specific seismic hazard using Ground Motion Prediction Equations (GMPEs) to estimate seismically induced ground motions at the site. Seismic hazard analyses were previously conducted for the design of the Cell 4A and 4B facilities (Tetra Tech, 2006; Tetra Tech, 2010) and in response to DWMRC review of EFRI responses to interrogatories on the Reclamation Plan (MWH, 2012). These analyses indicated that the seismic hazard at the site is dominated by background events in the Colorado Plateau.

The PSHA is based on a seismotectonic model and source characterization of the site and surrounding area. The study evaluated a 200-mile radius surrounding the site. The seismotectonic model identified three general seismic sources in the study area: 1) seismicity of the Intermountain Seismic Belt (ISB), 2) seismicity of the Colorado Plateau (CP), and 3) crustal faults that meet the NRC minimum criteria. Each source zone was characterized to establish input parameters for the seismic hazard analyses. The PSHA was performed using HAZ43 (2014) software developed by Dr. Norman Abrahamson. Operational and long-term design recommendations were developed based on the results from this PSHA and previous seismic investigations at the site.

This study concluded that the maximum horizontal acceleration value at the Mill site for a seismic event associated with an average return period of 10,000 years is 0.15g. Based on this maximum horizontal acceleration, a pseudo-static coefficient of 0.10g was used for seismic stability analyses of the reclaimed tailings impoundments (presented in Appendix A).

1.7 Biota (1978 ER Section 2.9)

1.7.1 Terrestrial (1978 ER Section 2.9.1)

1.7.1.1 Flora (1978 ER Section 2.9.1.1)

The natural vegetation presently occurring within a 25-mile (40-km) radius of the site is very similar to that of the potential, being characterized by pinyon-juniper woodland intergrading with big sagebrush (*Artemisia tridentata*) communities. The pinyon-juniper community is dominated by Utah juniper (*Juniperus osteosperma*) with occurrences of pinyon pine (*Pinus edulis*) as a codominant or subdominant tree species. The understory of this community, which is usually quite open, is composed of grasses, forbs, and shrubs that are also found in the big sagebrush communities. Common associates include galleta grass (*Hilaria jamesii*), green ephedra (*Ephedra viridis*), and broom snakewood (*Gutierrezia sarothrae*). The big sagebrush communities occur in deep, well-drained soils on flat terrain, whereas the pinyon-juniper woodland is usually found on shallow rocky soil of exposed canyon ridges and slopes.

Seven community types are present on the Mill site (Table 1.7-1 and Figure 1.7-1). Except for the small portions of pinyon-juniper woodland and the big sagebrush community types, the majority of the plant communities within the site boundary have been disturbed by past grazing and/or treatments designed to improve the site for rangeland. These past treatments include chaining, plowing, and reseeding with crested wheatgrass (*Agropyron desertorum*). Controlled big sagebrush communities are those lands containing big sagebrush that have been chained to stimulate grass production. In addition, these areas have been seeded with crested wheatgrass. Both grassland communities I and II are the result of chaining and/or plowing and seeding with crested wheatgrass. The reseeded grassland II community is in an earlier stage of recovery from disturbance than the reseeded grassland I community. The relative frequency, relative cover, relative density, and importance values of species sampled in each community are presented in Dames and Moore, (1978b), Table 2.8-2. The percentage of vegetative cover in 1977 was lowest on the reseeded grassland II community (10.7 percent) and highest on the big sagebrush community (33 percent) (Table 1.7-2).

Based upon dry weight composition, most communities on the site were in poor range condition in 1977 (Dames & Moore, 1978b, Tables 2.8-3 and 2.8-4). Pinyon-juniper, big sagebrush, and controlled big sagebrush communities were in fair condition. However, precipitation for 1977 at the Mill site was classed as drought conditions (Dames & Moore, 1978b, Section 2.8.2.1). Until July, no production was evident on the site.

Based on the work completed by Dames & Moore in the 1978 ER, no designated or proposed endangered plant species occur on or near the Mill site (Dames & Moore, 1978b, Section 2.8.2.1). Of the 65 proposed endangered species in Utah at that time, six have documented distributions on San Juan County. A review of the habitat requirements and known distributions of these species by Dames & Moore in the 1978 ER indicated that, because of the disturbed environment, these species would probably not occur on the Mill site. The Navajo Sedge has been added to the list as a threatened species since the 1978 ER.

VEGETATION COMMUNITY TYPES
ON THE WHITE MESA MILL SITE
FIGURE 1.7-1

Author: Date: May 1999 Drafted By: RAH

\\dmcfs0\MASTER DRAWINGS\USA\Utah\Mill\dwgs\Reclamation Plans\Rev_07-2011\Work01_Harold\Fig.1.7-1_Vegetation.dwg Layout1 GMoseley

In completing the 2002 EA, NRC staff contacted wildlife biologists from the BLM and the Utah Wildlife Service to gather local information on the occurrences of additional species surrounding the Mill. In the 2002 EA, NRC staff concluded that the Navajo Sedge has not been observed in the area surrounding Blanding, and is typically found in areas of moisture (2002 EA).

In June 2012, the area surrounding the Mill site was surveyed for plant composition to supplement data presented in Dames & Moore (1978b). Survey results confirmed that two principal plant community types in the vicinity of the Mill site. These plant communities are Big Sagebrush shrubland and Juniper woodland. In addition to these two principal plant community types, there are a number of disturbed areas in different stages of successional development. These areas reflect past disturbances such as sagebrush removal (chaining and plowing) and seeding and intense grazing, as evidenced by a complete lack of any understory species in some areas. The vegetation survey conducted in 2012 provides information of species that exist on the Mill site and their relative importance in terms of plant cover. All areas surveyed in 2012 show that big sagebrush (*Artemisia tridentata*) is the dominant species and subdominants are either broom snakeweed (*Gutierrezia sarothroae*) or galleta (*Hilaria jamesii*). Additional discussion on this survey is provided in Appendix A.

1.7.1.2 Fauna (1978 ER Section 2.9.1.2)

Wildlife data have been collected through four seasons at several locations on the site. The presence of a species was based on direct observations, trappings and signs such as the occurrence of scat, tracks, or burrows. A total of 174 vertebrate species potentially occur within the vicinity of the mill (Dames & Moore, 1978b, Appendix D), 78 of which were confirmed (Dames & Moore, 1978b, Section 2.8.2.2).

Although seven species of amphibians are thought to occur in the area, the scarcity of surface water limits the use of the site by amphibians. The tiger salamander (*Ambystoma tigrinum*) was the only species observed. It appeared in the pinyon-juniper woodland west of the Mill site (Dames & Moore, 1978b, Section 2.8.2.2).

Eleven species of lizards and five snakes potentially occur in the area. Three species of lizards were observed: the sagebrush lizard (*Sceloparas graciosus*), western whiptail (*Cnemidophorus tigris*), and the short-horned lizard (*Phrynosoma douglassi*) (Dames & Moore, 1978b, Section 2.8.2.2). The sagebrush and western whiptail lizard were found in sagebrush habitat, and the short-horned lizard was observed in the grassland. No snakes were observed during the field work.

Fifty-six species of birds were observed in the vicinity of the Mill site (Table 1.7-3). The abundance of each species was estimated by using modified Emlen transects and roadside bird counts in various habitats and seasons. Only four species were observed during the February sampling. The most abundant species was the horned lark (*Eremophila aepestis*) followed by the common raven (*Corvus corax*), which were both concentrated in the grassland. Avian counts increased drastically in May. Based on extrapolation of the Emlen transect data, the avian density on grassland of the Mill site during spring was about 123 per 100 acres (305 per square kilometer). Of these individuals, 94 percent were horned larks and western meadowlarks (*Sturnella neglecta*). This density and species composition are typical of rangeland habitats. In late June the species diversity declined somewhat in grassland but peaked in all other habitats. By October the overall diversity decreased but again remained the highest in grassland.

Source: Dames & Moore (1978b), Table 2.8-5

Raptors are prominent in the western United States. Five species were observed in the vicinity of the site (Table 1.7-3). Although no nests of these species were located, all (except the golden eagle, *Aquila chrysaetos*) have suitable nesting habitat in the vicinity of the site. The nest of a prairie falcon (*Falco mexicanus*) was found about 3/4 mile (1.2 km) east of the site. Although no sightings were made of this species, members tend to return to the same nests for several years if undisturbed (Dames & Moore, 1978b, Section 2.8.2.2).

Of several mammals that occupy the site, mule deer (*Odocoileus hemionus*) is the largest species. The deer inhabit the project vicinity and adjacent canyons during winter to feed on the sagebrush and have been observed migrating through the site to Murphy Point (Dames & Moore, 1978b, Section 2.8.2.2). Winter deer use of the project vicinity, as measured by browse utilization, is among the heaviest in southeastern Utah [25 days of use per acre (61 days of use per hectare) in the pinyon-juniper-sagebrush habitats in the vicinity of the Mill site]. In addition, this area is heavily used as a migration route by deer traveling to Murphy Point to winter. Daily movement during winter periods by deer inhabiting the area has also been observed between Westwater Creek and Murphy Point. The present size of the local deer herd is not known.

Other mammals present at the site include the coyote (*Canis latrans*), red fox (*Vulpes vulpes*), gray fox (*Urocyon cineroargenteus*), striped skunk (*Mephitis mephitis*), badger (*taxidea taxus*), longtail weasel (*Mustela frenata*), and bobcat (*Lynx rufus*). Nine species of rodents were trapped or observed on the site, the deer mouse (*Peromyscus maniculatus*) having the greatest distribution and abundance. Although desert cottontails (*Sylvilagus auduboni*) were uncommon in 1977, black-tailed jackrabbits (*Lepus californicus*) were seen during all seasons.

In the 2002 EA, NRC staff noted that, in the vicinity of the site, the U.S. Fish and Wildlife Service had provided the list set out in Table 3.12-1 of the 2002 EA, of the endangered, threatened, and candidate species that may occur in the area around the site.

Table 1.7-4
Endangered, Threatened and Candidate Species in the Mill Area

Common Name	Scientific Name	Status
Navajo Sedge	*Carex specuicola*	Threatened
Bonytail Chub	*Gila elegans*	Endangered
Colorado Pikeminnow	*Ptychocheilus Lucius*	Endangered
Humpback Chub	*Gila cypha*	Endangered
Razorback Sucker	*Xyrauchen texanus*	Endangered
Bald Eagle	*Haliaeetus leucocephalus*	Threatened
California Condor	*Gymnogyps californianus*	Endangered
Gunnison Sage Grouse	*Centrocercus minimus*	Candidate
Mexican Spotted Owl	*Strix occidentalis lucida*	Threatened
Southwestern Willow Flycatcher	*Empidonax traillii extimus*	Endangered
Western Yellow-billed Cuckoo	*Coccyzus americanus occidentalis*	Candidate
Black-footed Ferret	*Mustela nigripes*	Endangered

Source: 2002 EA (NRC, 2002)

The 2002 EA also noted that, in addition, the species listed on Table 3.12-2 of the 2002 EA may occur within the Mill area that are managed under Conservation Agreements/Strategies.

Table 1.7-5
Species Managed Under Conservation Agreements/Strategies at the Mill Area

Common Name	Scientific Name
Colorado River Cutthroat Trout	*Oncorhynchus clarki pleuriticus*
Gunnison Sage Grouse	*Centrocercus minimus*

Source: 2002 EA (NRC, 2002)

For the 2002 EA, NRC staff contacted wildlife biologists from the BLM and the Utah Wildlife Service to gather local information on the occurrences of these additional species surrounding the Mill. NRC staff made the following conclusions (2002 EA p. 4):

> While the ranges of the bald eagle, peregrine falcon, and willow flycatcher encompass the project area, their likelihood of utilizing the site is extremely low. The black-footed ferret has not been seen in Utah since 1952, and is not expected to occur any longer in the area. The California Condor has only rarely been spotted in the area of Moab, Utah, (70 miles north) and around Lake Powell (approximately 50 miles south). The Mexican Spotted Owl is only found in the mountains in Utah, and is not expected to be on the Mesa. The Southwestern Willow Flycatcher, Western Yellow-billed Cuckoo, and Gunnison Sage Grouse are also not expected to be found in the immediate area around the Mill site.

1.7.2 Aquatic Biota (*1978 ER Section 2.9.2*)

Aquatic habitat at the Mill site ranges temporally from extremely limited to nonexistent due to the aridity, topography and soil characteristics of the region and consequent dearth of perennial surface water. Two small stock watering ponds, are located on the Mill site a few hundred yards from the ore pad area (see Figure 1.5-3). One additional small "wildlife pond", east of Cell 4A, was completed in 1994 to serve as a diversionary feature for migrating waterfowl (see Figure 1.5-3). Although more properly considered features of the terrestrial environment, they essentially represent the total aquatic habitat on the Mill site. These ponds probably harbor algae, insects, other invertebrate forms, and amphibians.

They also provide a water source for small mammals and birds. Similar ephemeral catch and seepage basins are typical and numerous to the northeast of the Mill site and south of Blanding.

Aquatic habitat in the project vicinity is similarly limited. The three adjacent streams (Corral Creek, Westwater Creek, and an unnamed arm of Cottonwood Wash) are only intermittently active, carrying water primarily in the spring during increased rainfall and snowmelt runoff, in the autumn, and briefly during localized but intense electrical storms. Intermittent water flow most typically occurs in April, August, and October in those streams. Again, due to the temporary nature of these steams, their contribution to the aquatic habitat of the region is probably limited to providing a water source for wildlife and a temporary habitat for insect and amphibian species.

In the 2002 EA, NRC staff concluded that (p. 4) no populations of fish are present on the project site, nor are any known to exist in the immediate area of the site. Four species of fish designated as endangered or threatened (the Bonytail Chub, Colorado Pikeminnow, Humpback Chub and Razorback Sucker) occur in the San Juan River 18 miles south of the site, which Dames & Moore noted in the 1978 ER (Section 2.8.2) is the closest habitat suitable for these species. NRC staff further concluded that there are no discharges of

Mill effluents to surface waters, and therefore, no impacts are expected for the San Juan River due to operations of the Mill.

1.7.3 Background Radiation (*2007 ER, Section 3.13.1*)

All living things are continuously exposed to ionizing radiation from a variety of sources including cosmic and cosmogenic radiation from space and external radiation from terrestrial radionuclides such as uranium, thorium and potassium-40 that occur in the earth's crust, in building materials, in the air we breathe, the food we eat, the water we drink and in our bodies.

Some exposures, such as that from potassium-40, are controlled by our body's metabolism and are relatively constant throughout the world, but exposures from sources such as uranium and thorium in soils and especially from radon in homes can vary greatly, by more than a factor of ten, depending on location.

In order to provide a context for exposures potentially attributable to radioactive emissions from processing ores and alternate feed materials at the Mill, this section provides some general background information on exposures to natural background radiation worldwide, in the United States and in the Colorado Plateau region where the Mill is located.

1.7.3.1 The World

In general terms, the worldwide breakdown of natural background radiation sources can be summarized as follows (UNSCEAR, 2000):

Cosmic and Cosmogenic	39 mrem/yr
Terrestrial	48 mrem/yr
Inhaled (Radon)	126 mrem/yr
Ingested	29 mrem /yr
Total (Average)	**242 mrem/yr (116 mrem/yr excluding radon)**

According to the United Nations Scientific Committee on the Effects of Atomic Radiation ("UNSCEAR"), the actual doses can vary considerably from the nominal values listed above, and around the world vary from this value by more than a factor of 10. For example, the dose from cosmic and cosmogenic radiation varies with altitude. The higher the altitude, the less is the protection offered by the earth's atmosphere. The dose from external gamma radiation can vary greatly depending on the levels of uranium and thorium series radionuclides in the local soil. One example is the elevated gamma fields seen on natural sands containing heavy minerals as for example in regions around the Indian Ocean, in Brazil, and New Jersey. The high variability in indoor radon concentrations is a major source of the variation in natural background dose. The variability in the dose from radon arises from many factors, including: variability in soil radium concentrations from place to place; variation both over time and location in housing stock, heating and ventilating systems; and variations in individual habits. The worldwide average ambient (i.e. outdoor) radon concentration is about 10 Bq/m^3 (UNSCEAR, 2000) and the world average concentration of U-238 and Th-232 in soils is about 0.7 pCi/g (25 Bq/kg) (NRC, 1994).

The definition of "background radiation" in 10 CFR 20.1003 specifically includes global fallout as it exists in the environment from the testing of nuclear explosive devices or from past nuclear accidents such as Chernobyl that contribute to background radiation and are not under the control of the licensee. The calculation of background radiation in Section 3.13.1 of the 2007 ER is conservative because it does not include such fallout in background radiation for the Mill site.

1.7.3.2 United States

In the United States, nominal average levels of natural background radiation are as follows (National Council of Radiation Protection and Measurements ("NCRP"), 1987):

Cosmic and Cosmogenic	28 mrem/yr
Terrestrial	28 mrem/yr
Inhaled (Radon)	200 mrem/yr
Ingested	40 mrem /yr
Total (Average)	**296 mrem/yr (96 mrem/yr excluding radon)**

As shown above, in the United States, the average annual dose from natural background radiation is about 296 mrem/yr (including radon). The actual annual dose from natural background varies by region within the United States. For example, the average dose from external terrestrial radiation for a person living on the Colorado Plateau is in the order of 63 mrem/yr, which is considerably higher than the average dose from terrestrial radiation for a person living in Florida, where the average annual dose from external terrestrial radiation is only about 16 mrem/yr. (NRC, 1994; NCRP, 1987). In the United States, outdoor radon levels vary widely from about 0.1 pCi/l in New York City to about 1.2 pCi/L in Colorado Springs (NCRP, 1987), generally consistent with nominal worldwide values noted in the previous section.

1.7.4 Mill Site Background (*1978 ER Section 2.10*)

Radiation exposure in the natural environment is due to cosmic and terrestrial radiation and to the inhalation of radon and its daughters. Measurements of the background environmental radioactivity were made at the Mill site using thermoluminescent dosimeters ("TLDs"). The results indicate an average total body dose of 142 millirems per year, of which 68 millirems is attributable to cosmic radiation and 74 millirems to terrestrial sources. The cosmogenic radiation dose is estimated to be about 1 millirem per year. Terrestrial radiation originates from the radionuclides potassium-40, rubidium-87, and daughter isotopes from the decay of uranium-238, thorium-232, and, to a lesser extent, uranium-235. The dose from ingested radionuclides is estimated at 18 millirems per year to the total body. The dose to the total body from all sources of environmental radioactivity is estimated to be about 161 millirems per year.

The concentration of radon in the area is estimated to be in the range of 500 to 1,000 pCi/m^3, based on the concentration of radium-226 in the local soil. Exposure to this concentration on a continuous basis would result in a dose of up to 625 millirems per year to the bronchial epithelium. As ventilation decreases, the dose increases; for example, in unventilated enclosures, the comparable dose might reach 1,200 millirems per year.

The medical total body dose for Utah is about 75 millirems per year per person. The total dose in the area of the mill from natural background and medical exposure is estimated to be 236 millirems per year.

1.7.5 Current Monitoring Data

The most recent data for gamma, vegetation, air and stack sampling, groundwater, surface water, meteorological monitoring, and soil sampling discussed in the following sections are found in the Semi-Annual Effluent Report for July through December 2015. See Section 2.3.2.1 for a more detailed discussion of the environmental monitoring programs at the Mill.

1.7.5.1 Environmental Radon

Environmental radon concentrations are determined by using Track Etch detectors. There is one detector at each of eight environmental monitoring stations with a duplicate at BHV-2. See the Semi-Annual Effluent reports, for maps showing these locations.

1.7.5.2 Environmental Gamma

Gamma radiation levels are determined by optically stimulated luminescence dosimeters ("OSLs"). The OSLs are placed at the eight environmental stations located around the perimeter boundary of the Mill site discussed above. The badges are exchanged quarterly. Recent data are presented in the Semi-Annual Effluent Report for July through December 2015.

1.7.5.3 Vegetation Samples

Vegetation samples are collected at three locations around the Mill periphery. The sampling locations are northeast, northwest, and southwest of the Mill facility. Vegetation samples are collected three times per year. Recent vegetation results are included in the Semi-Annual Effluent Report for July through December 2015. No trends are apparent, as concentrations at each sampling location have remained consistent.

1.7.5.4 Environmental Air Monitoring and Stack Sampling

Air monitoring at the Mill is conducted at seven high volume (40 standard cubic feet per minute) stations located around the periphery of the Mill. These locations are shown on Figure 2.3-2. BHV-1 and BHV-8 are located at the northern Mill boundary. BHV-2 is further north at the nearest residence. BHV-4 is south of Cell 3, BHV-5 is just south of the ore storage pad on the eastern boundary of the Mill property, BHV-6 is located on a vector between the Mill site and the White Mesa Ute Community, and BHV-7 is located on the eastern boundary of the Mill north of BHV-5. The Semi-Annual Effluent Reports contain air monitoring data. The results of the quarterly stack samples are also presented in the Semi-Annual Effluent Reports.

Pursuant to NRC License Amendment No. 41 for the Mill's Source Material License No. SUA-1358, air particulate radionuclide monitoring at BHV-3 was discontinued at the end of the third quarter of 1995. Tables in the Semi-Annual Effluent Reports show the radionuclide concentrations at each location. No trends are evident.

1.7.5.5 Surface Water

The results of surface water monitoring are presented in the Semi-Annual Effluent Reports. Cottonwood Creek is sampled semi-annually and Westwater Creek is sampled on an annual basis. No trends are apparent.

1.7.5.6 Meteorological Monitoring

The Semi-Annual Air Quality and Meteorology Monitoring Report for July 1, 2015 through December 31, 2015 was provided by McVehil-Monnett and is available at the Mill.

2 EXISTING FACILITY

The following sections describe the construction history of the Mill; the Mill and Mill tailings management facilities; Mill operations including the Mill circuit and tailings management; and both operational and environmental monitoring.

2.1 Facility Construction History

The Mill is a uranium/vanadium mill that was developed in the late 1970s by Energy Fuels Nuclear, Inc. ("EFN") as an outlet for the many small mines that are located in the Colorado Plateau and for the possibility of milling Arizona Strip ores. At the time of its construction, it was anticipated that high uranium prices would stimulate ore production. However, prices started to decline about the same time as Mill operations commenced.

As uranium prices fell, producers in the region were affected and mine output declined. After about two and one-half years, the Mill ceased ore processing operations altogether, began solution recycle, and entered a total shutdown phase. In 1984, a majority ownership interest was acquired by Union Carbide Corporation's ("UCC") Metals Division which later became Umetco Minerals Corporation ("Umetco"), a wholly-owned subsidiary of UCC. This partnership continued until May 26, 1994 when EFN reassumed complete ownership. In May 1997, Denison (then named International Uranium (USA) Corporation) and its affiliates purchased the assets of EFN. EFRI purchased Denison in July 2012 and is the current owner of the facility.

2.1.1 Mill and Mill Tailings System

The Source Materials License Application for the Mill was submitted to the NRC on February 8, 1978. Between that date and the date the first ore was fed to the Mill grizzly on May 6, 1980, several actions were taken including: increasing Mill design capacity, permit issuance from the United States Environmental Protection Agency ("EPA") and the State of Utah, archeological clearance for the Mill and tailings system, and an NRC pre-operational inspection on May 5, 1980.

Construction on the Mill tailings system began on August 1, 1978 with the movement of earth from the area of Cell 2. Cell 2 was completed on May 4, 1980, Cell 1 on June 29, 1981, and Cell 3 on September 2, 1982. In January 1990 an additional cell, designated Cell 4A, was completed and initially used solely for solution storage and evaporation. Cell 4A was only used for a short time and then taken out of service because of concerns about the synthetic lining system. In 2007, Cell 4A was retrofitted with a new State of Utah approved lining system and was authorized to begin accepting process solutions in September 2008. Cell 4A was put back into service in October 2008. Cell 4B was constructed in 2010 and authorized to begin accepting process solutions in February 2011.

2.2 Facility Operations

In the following subsections, an overview of Mill operations and operating periods are followed by descriptions of the operations of the Mill circuit and tailings management facilities.

2.2.1 Operating Periods

The Mill was operated by EFN from the initial start-up date of May 6, 1980 until the cessation of operations in 1983. Umetco, as per agreement between the parties, became the operator of record on January 1, 1984.

The Mill was shut down during all of 1984. The Mill operated at least part of each year from 1985 through 1990. Mill operations again ceased during the years of 1991 through 1994. EFN reacquired sole ownership on May 26, 1994, and the Mill operated again during 1995 and 1996. After acquisition of the Mill by Denison and its affiliates several local mines were restarted and the Mill processed conventional ore during 1999 and early 2000. With the resurgence in uranium and vanadium prices in 2003, Denison reopened several area mines and again began processing uranium and vanadium ores in April 2008. Mill operations were suspended in May 2009, and resumed in March 2010. Conventional ore processing was again suspended in July 2011, resumed in November 2011 through March 2012, and suspended in April 2012. Denison became EFRI after July 25, 2012. Conventional ore processing resumed from August 2012 through June 2013, was suspended in July 2013, resumed May 2014 through August 2014, and was suspended again in September 2014. Typical employment figures for the Mill are approximately 110 during uranium-only operations and 150 during uranium/vanadium operations.

Commencing in the early 1990s through today, the Mill has processed alternate feed materials from time to time when the Mill has not been processing conventional ores. Alternate feed materials are uranium-bearing materials other than conventionally mined uranium ores. The Mill installed an alternate feed circuit in 2009 that allows the Mill to process certain alternate feed materials simultaneously with conventional ores.

2.2.2 Mill Circuit

While originally designed for a capacity of 1,500 dry tons per day (dtpd), the Mill capacity was boosted to the present rated design of 1,980 dtpd prior to commissioning.

The Mill uses an atmospheric hot acid leach followed by counter current decantation (CCD). This in turn is followed by a clarification stage which precedes the solvent extraction (SX) circuit. Kerosene containing iso-decanol and tertiary amines extracts the uranium and vanadium from the aqueous solution in the SX circuit. Salt and soda ash are then used to strip the uranium and vanadium from the organic phase.

After extraction of the uranium values from the aqueous solution in SX, uranium is precipitated with anhydrous ammonia, dissolved, and re-precipitated to improve product quality. The resulting precipitate is then washed and dewatered using centrifuges to produce a final product called "yellowcake." The yellowcake is dried in a multiple hearth dryer and packaged in drums weighing approximately 800 to 1,000 lbs. for shipping to converters.

After the uranium values are stripped from the pregnant solution in SX, the vanadium values are transferred to tertiary amines contained in kerosene and concentrated into an intermediate product called vanadium product liquor (VPL). An intermediate product, ammonium metavanadate (AMV), is precipitated from the VPL using ammonium sulfate in batch precipitators. The AMV is then filtered on a belt filter and, if necessary, dried. Normally, the AMV cake is fed to fusion furnaces where it is converted to the Mill's primary vanadium product, V_2O_5 tech flake, commonly called "black flake."

The same basic process steps used for the recovery of uranium from conventional ores are used for the recovery of uranium from alternate feed materials, with some variations depending on the particular alternate feed material.

The Mill processed 1,511,544 tons of conventional ore and other materials from May 6, 1980 to February 4, 1983. During the second operational period from October 1, 1985 through December 7, 1987, 1,023,393 tons of conventional ore were processed. During the third operational period from July 1988 through

November 1990, 1,015,032 tons of conventional ore were processed. During the fourth operational period from August 1995 through January 1996, 203,317 tons of conventional ore were processed. In the fifth operational period, from May 1996 through September 1996, the Mill processed 3,868 tons of calcium fluoride alternate feed material. From 1997 to early 1999, the Mill processed 58,403 tons from several additional alternate feed stocks.

With rising uranium prices in the late 1990s, company mines were reopened in 1997, and 87,250 tons of conventional ore were processed in 1999 and early 2000. In 2002 and 2003, the Mill processed 266,690 tons of alternate feed material from government cleanup projects. An additional 40,866 tons of alternate feed materials were processed in 2007. An additional 1,401 tons of alternate feed materials were processed from 2008 through July 2011. From April 2008 through July 2011 the Mill processed an additional 722,843 tons of conventional ore. The Mill processed 340,058 and 24,036 tons of conventional ore and alternate feed materials, respectively, between August 2011 and March 2016.

Inception to date material processed through March 2016 totals 5,298,701 tons. This total is for all processing periods and feeds combined.

2.2.3 Tailings Management Facilities

Tailings produced by the Mill from conventional ores typically contain 30 percent moisture by weight, have an in-place dry density of 86.3 pounds per cubic foot (calculated from Cell 2 volume and tons placed), have a size distribution with a significant -200 to -325 mesh size fraction, and have a high acid and flocculent content. Tailings from alternate feed materials that are similar physically to conventional ores, which comprise most of the tons of alternate feed materials processed to date at the Mill, are similar to the tailings for conventional ores. Tailings from some of the higher grade, lower volume alternate feed materials may vary somewhat from the tailings from conventional ores, primarily in moisture and density content.

The tailings facilities at the Mill currently consist of five cells as follows:

- Cell 1, constructed with a 30 mil PVC earthen-covered liner, is used for the evaporation of process solutions (Cell 1 was previously referred to as Cell 1-I).
- Cell 2, constructed with a 30 mil PVC earthen-covered liner, is used for the storage of barren tailings sands. This Cell is full and has been partially reclaimed.
- Cell 3, constructed with a 30 mil PVC earthen-covered liner, is used for the storage of barren tailings sands and process solutions, but currently only receives mill waste and byproduct material in accordance with License provisions. This cell is partially filled and has been partially reclaimed.
- Cell 4A, constructed with a geosynthetic clay liner, a 60 mil HDPE liner, a 300 mil HDPE geonet drainage layer, a second 60 mil HDPE liner, and a slimes drain network over the entire cell bottom. This cell was placed into service in October 2008 and is used for storage of barren tailings sands and evaporation of process solutions.
- Cell 4B, constructed with a geosynthetic clay liner, a 60 mil HDPE liner, a 300 mil HDPE geonet drainage layer, a second 60 mil HDPE liner, and a slimes drain network over the entire cell bottom. This cell was placed into service in February 2011, is used for evaporation of process solutions, and has not been used for tailings storage.

Total estimated design capacity of Cells 2, 3, 4A, and 4B is approximately eight million tons. Figures 1.5-4 and 1.5-5 show the locations of the tailings management system cells.

2.2.3.1 Tailings Management

Constructed in shallow valleys or swale areas, the lined tailings facilities provide storage below the existing grade and reduce potential exposure. Because the cells are separate and distinct, individual tailings cells may be reclaimed as they are filled to capacity. This phased reclamation approach minimizes the amount of tailings exposed at any given time and reduces potential exposure to a minimum.

Slurry disposal has taken place in Cells 2, 3 and 4A. Tailings placement in Cell 2 and Cell 3 was accomplished by means of the final grade method, described below.

The final grade method used in Cell 2 and Cell 3 calls for the slurry to be discharged until the tailings surface comes up to near final grade. The discharge points are set up in the east end of the cell, and the final grade surface is advanced to the slimes pool area. Coarse tailings sand from the discharge points is graded into low areas to reach the final disposal elevation. When the slimes pool is reached, the discharge points are then moved to the west end of the cell and worked back to the middle. An advantage to using the final grade method is that maximum beach stability is achieved by (1) allowing water to drain from the sands to the maximum extent, and (2) allowing coarse sand deposition to help provide stable beaches. Another advantage is that radon release and dust prevention measures (through the placement of the initial layer of the final cover) are applied as expeditiously as possible.

Slurry disposal in Cell 4A is from several pre-determined discharge points located around the north and east sides of the cell. Slurry discharge is only allowed on skid pads, or protective HDPE sheets, to prevent damage to the synthetic lining system. Once tailings solids have reach the maximum elevation around the perimeter of the cell, discharge points can be moved toward the interior of the cell. Slurry disposal in Cell 4B will be conducted in the same manner as Cell 4A. Cell 4B is currently only accepting process solutions.

2.2.3.2 Liquid Management

As a zero-discharge facility, the Mill must evaporate all of the liquids utilized during processing. This evaporation currently takes place in four areas:

- Cell 1, which is used for solutions only
- Cell 3, in which tailings and solutions exist
- Cell 4A, in which tailings and solutions exist
- Cell 4B, presently used for solutions only

The original engineering design indicated a net water gain into the cells would occur during Mill operations. As anticipated, this has been proven to be the case. In addition to natural evaporation, spray systems have been used at various times to enhance evaporative rates and for dust control. To minimize the net water gain, solutions are recycled back for use in the Mill circuit from the active tailings cells to the maximum extent possible. Solutions from Cells 1, 3, 4A, and 4B are brought back to the CCD circuit where metallurgical benefit can be realized. Recycle to other parts of the Mill circuit are not feasible due to the acidic condition of the solution.

2.3 Monitoring Programs

2.3.1 Monitoring and Reporting Under the Mill's GWDP

2.3.1.1 Groundwater Monitoring

a) Plugged and Excluded Wells

Wells MW-6, MW-7, and MW-8 were plugged because they were in the area of Cell 3, as was MW-13, in the Cell 4A area. Wells MW-9 and MW-10 are dry and have been excluded from the monitoring program. MW-16 is dry and has been plugged as part of the tailings Cell 4B construction.

b) Groundwater Monitoring at the Mill Prior to Issuance of the GWDP

At the time of renewal of the License by NRC in March 1997 and up until issuance of the GWDP in March 2005, the Mill implemented a groundwater detection monitoring program to ensure compliance to 10 CFR Part 40, Appendix A, in accordance with the provisions of the License. The detection monitoring program was in accordance with the report entitled, *Points of Compliance, White Mesa Uranium Mill*, prepared by Titan Environmental Corporation, submitted by letter to the NRC dated October 5, 1994 (Titan, 1994b). Under that program, the Mill sampled monitoring wells MW-5, MW-11, MW-12, MW-14, MW-15 and MW-17, on a quarterly basis. Samples were analyzed for chloride, potassium, nickel and uranium, and the results of such sampling were included in the Mill's Semi-Annual Effluent Monitoring Reports that were filed with the NRC up until August 2004 and with the DWMRC subsequent thereto.

Between 1979 and 1997, the Mill monitored up to 20 constituents in up to 13 wells. That program was changed to the Points of Compliance Program in 1997 because NRC had concluded that:

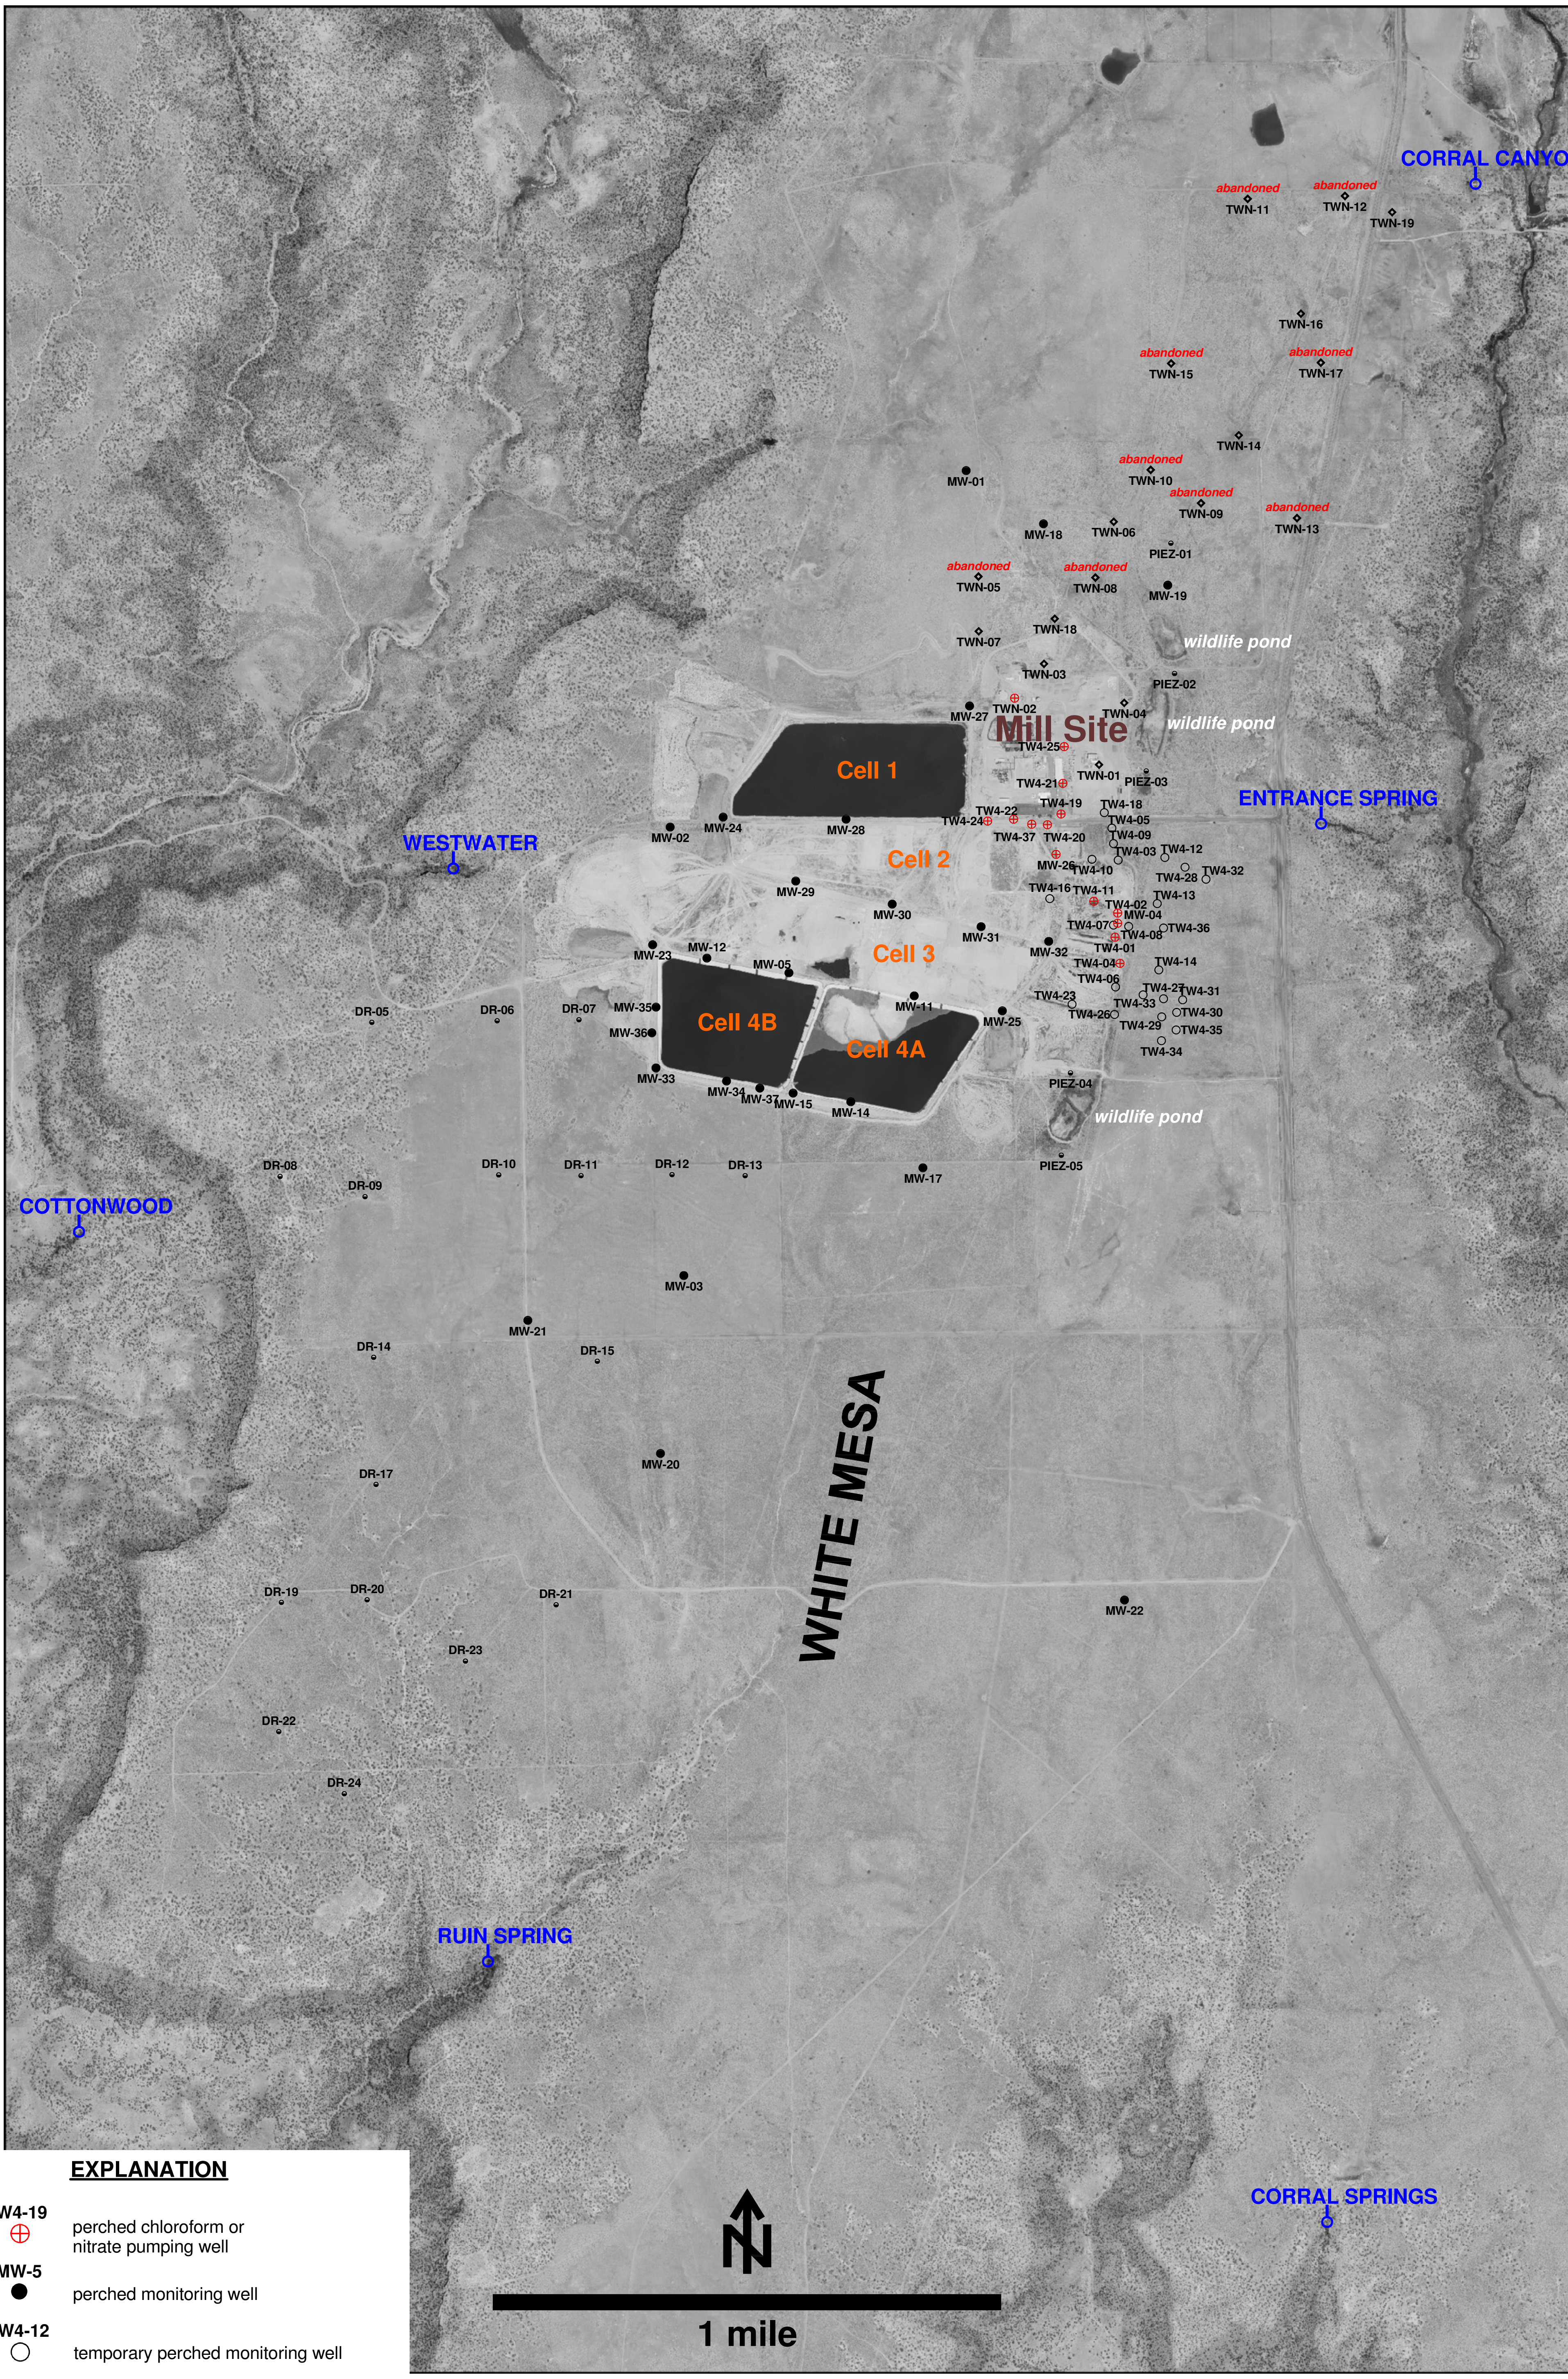
- The Mill and tailings system had produced no impacts to the perched zone or deep aquifer
- The most dependable indicators of water quality and potential cell failure were considered to be chloride, nickel, potassium and natural uranium

c) Issuance of the GWDP

On March 8, 2005, the DWMRC issued the GWDP, which includes a groundwater monitoring program that supersedes and replaces the groundwater monitoring requirements set out in the License. Groundwater monitoring under the GWDP commenced in March 2005, the results of which are included in the Mill's *Quarterly Groundwater Monitoring Reports* that are submitted to the DWMRC.

d) Current Ground Water Monitoring Program at the Mill Under the GWDP

The current groundwater monitoring program at the Mill under the GWDP consists of monitoring at 25 point of compliance monitoring wells: MW-1, MW-2, MW-3, MW-3A, MW-5, MW-11, MW-12, MW-14, MW-15, MW-17, MW-18, MW-19, MW-23, MW-24, MW-25, MW-26, MW-27, MW-28, MW-29, MW-30, MW-31, MW-32 MW-35, MW-36, and MW-37. The locations of these wells are indicated on Figure 2.3-1.



EXPLANATION

Symbol	Description
TW4-19	perched chloroform or nitrate pumping well
MW-5	perched monitoring well
TW4-12	temporary perched monitoring well
TWN-7	temporary perched nitrate monitoring well
PIEZ-1	perched piezometer
RUIN SPRING	seep or spring

HYDRO GEO CHEM, INC.

WHITE MESA SITE PLAN SHOWING LOCATIONS OF PERCHED WELLS AND PIEZOMETERS

APPROVED	DATE	REFERENCE	FIGURE
		H:/718000/ ReclamationPlan/Uwelloc0316_Rec.srf	2.3-1

Part I.E.1.(c) of the GWDP requires that each point of compliance well must be sampled for the constituents listed in Table 2.3-1.

Table 2.3-1
Groundwater Monitoring Constituents Listed in Table 2 of the GWDP

Nutrients:		
Ammonia (as N)	Nitrate & Nitrite (as N)	
Heavy Metals:		
Arsenic	Lead	Thallium
Beryllium	Manganese	Tin
Cadmium	Mercury	Uranium
Chromium	Molybdenum	Vanadium
Cobalt	Nickel	Zinc
Copper	Selenium	
Iron	Silver	
Radiologics:		
Gross Alpha		
Volatile Organic Compounds:		
Acetone	Chloroform	Tetrahydrofuran
Benzene	Chloromethane	Toluene
2-Butanone (MEK)	Dichloromethane	Xylenes (total)
Carbon Tetrachloride	Naphthalene	
Others:		
Field pH (S.U.)	Chloride	TDS
Fluoride	Sulfate	

Further, Part I.E.1.(d) of the GWDP requires that, in addition to pH, the following field parameters must also be monitored:

- Depth to groundwater
- Temperature
- Specific conductance
- Redox potential

and that, in addition to chloride and sulfate, the following general organics must also be monitored:

- Carbonate, bicarbonate, sodium, potassium, magnesium, calcium, and total anions and cations

Sample frequency depends on the speed of ground water flow in the vicinity of each well. Parts I.E.1(b) and (c) of the GWDP provide that quarterly monitoring is required for all wells where local groundwater average linear velocity has been found by the DWMRC to be equal to or greater than 10 feet/year, and semi-annual monitoring is required where the local groundwater average linear velocity has been found by the DWMRC to be less than 10 feet/year.

Based on these criteria, MW-11, MW-14, MW-25, MW-26, MW-30, MW-31, MW-35, MW-36 and MW-37 are monitored quarterly. Semi-annual monitoring is required at MW-1, MW-2, MW-3, MW-3A, MW-5, MW-12, MW-15, MW-17, MW-18, MW-19, MW-23, MW-24, MW-27, MW-28, MW-29 and MW-32.

In addition MW-20 and MW-22, which have been classified as general monitoring wells are sampled semi-annually.

2.3.1.2 Deep Aquifer

The culinary well (one of the supply wells) is completed in the Navajo aquifer, at a depth of approximately 1,800 feet below the ground surface. Due to the fact that the deep confined aquifer at the site is hydraulically isolated from the shallow perched aquifer (see the discussion in Sections 1.5.1.1 and 1.5.1.2) no monitoring of the deep aquifer is required under the GWDP.

2.3.1.3 Seeps and Springs

Pursuant to Part I.E.6 of the GWDP, EFRI has a *Sampling Plan for Seeps and Springs in the Vicinity of the White Mesa Uranium Mill*, Revision: 0, March 17, 2009 (EFRI, 2009, the “SSSP”) (and as modified on June 10, 2011, Revision 1 – submitted to UDEQ for review) that requires the Mill to perform groundwater sampling and analysis of all seeps and springs found downgradient or lateral gradient from the tailings management cells.

Under the SSSP, seeps and springs sampling is conducted on an annual basis between May 1 and July 15 of each year, to the extent sufficient water is available for sampling, at five identified seeps and springs near the Mill. The sampling locations were selected to correspond with those seeps and springs sampled for the initial Mill site characterization performed in the 1978 ER, plus additional sites located by EFRI, the BLM and Ute Mountain Ute Indian Tribe representatives.

Samples are analyzed for all groundwater monitoring parameters found in Table 2.3-1 and the general inorganic constituents specified for groundwater monitoring in Part I.E.1 (d). The laboratory procedures used to complete the analyses are those utilized for groundwater sampling. In addition to these laboratory parameters, the pH, temperature, redox potential, and conductivity of each sample will be measured and recorded in the field. Laboratories selected by EFRI to perform analyses of seeps and springs samples will be required to be certified by the State of Utah in accordance with UAC R317-6-6.12.A.

The seeps and springs sampling events are subject to the current Mill’s QAP, unless otherwise specifically modified by the SSSP to meet the specific needs of this type of sampling.

2.3.1.4 Discharge Minimization Technology and Best Available Technology Standards and Monitoring

a) General

Part I.D. of the GWDP sets out a number of Discharge Minimization Technology ("DMT") and Best Available Technology ("BAT") standards that must be followed. Part I.E. of the GWDP sets out the Groundwater Compliance and Technology Performance Monitoring requirements, to ensure that the DMT and BAT standards are met. These provisions of the GWDP, along with the *White Mesa Mill Discharge Minimization Technology (DMT) Monitoring Plan*, 4/15 Revision: 12.3 (the "DMT Plan") (EFRI, 2015a), the *White Mesa Mill Tailings Management System* (EFRI, 2015b), the Cell 4A and 4B BAT Monitoring, Operations and Maintenance Plan and other plans and programs developed pursuant to such Parts of the GWDP, set out the methods and procedures for inspections of the facility operations and for detecting failure of the system.

In addition to the programs discussed above, the following additional DMT and BAT performance standards and associated monitoring are required under Parts I.D and I.E. of the GWDP.

b) Tailings Cell Operation

Part I.D.2 of the GWDP provides that authorized operation and maximum disposal capacity in each of the existing tailings cells shall not exceed the levels authorized by the License and that under no circumstances shall the freeboard be less than three feet, as measured from the top of the flexible membrane liner ("FML"). Part I.E.7(a) of the GWDP requires that the wastewater pool elevations in Cells 1 and 3 must be monitored weekly to ensure compliance with the maximum wastewater elevation criteria mandated by Condition 10.3 of the License. Parts I.E.8 (a)(4) and I.E.12.(a)(4) provide that authorized operation and maximum disposal capacity in Cells 4A and 4B shall not exceed the levels authorized GWDP (as noted in the DMT Plan) and that under no circumstances shall the freeboard be less than three feet, as measured from the top of the FML. The requirements to meet freeboard elevation limits in Cell 3 and Cell 4A were eliminated upon approval to use Cell 4B. The solution elevation measurements in Cell 4A are not required for compliance with freeboard limits but are required for the calculation of the daily allowable volume of fluids pumped from Cell 4A LDS and are collected for this purpose.

Part I.D.2 further provides that any modifications by EFRI to any approved engineering design parameter at these existing tailings cells requires prior Directorapproval, modification of the GWDP and issuance of a construction permit.

c) Slimes Drain Monitoring

Part I.D.3(b)(1) of the GWDP requires that EFRI must at all times maintain the average wastewater head in the slimes drain access pipe to be as low as reasonably achievable (ALARA) in each tailings disposal cell, in accordance with the approved DMT Plan. Compliance will be achieved when the average annual wastewater recovery elevation in the slimes drain access pipe, determined pursuant to the currently approved DMT Plan meets the conditions in Equation 1 specified in Part I.D.3(b)(1) of the GWDP.

Part I.E.7(b) of the GWDP requires that EFRI must monitor and record quarterly the depth to wastewater in the slimes drain access pipes as described in the currently approved DMT Plan at Cell 2, and upon commencement of de-watering activities, at Cell 3, in order to ensure compliance with Part I.D.3(b)(1) of the GWDP.

d) Maximum Tailings Waste Solids Elevation

Part I.D.3(c) of the GWDP requires that upon closure of any tailings cell, EFRI must ensure that the maximum elevation of the tailings waste solids does not exceed the top of the FML.

e) Wastewater Elevation in Roberts Pond

Roberts Pond has been permanently removed from service. Excavation activities have been completed and pursuant to DWMRC correspondence dated March 5, 2015, routine monitoring is no longer necessary.

f) Inspection of Feedstock Storage Area

Part I.D.3(f) of the GWDP requires that open-air or bulk storage of all feedstock materials at the Mill facility awaiting Mill processing must be limited to the eastern portion of the Mill site (the "ore pad") described by the coordinates set out in that Part of the GWDP, and that storage of feedstock materials at the facility outside of this defined area, must meet the requirements of Part I.D.11 of the GWDP. Part I.D.11 requires that EFRI must store and manage feedstock materials outside the defined ore storage pad in accordance with the following minimum performance requirements:

(i) Feedstock materials will be stored at all times in water-tight containers, and

(ii) Aisle ways will be provided at all times to allow visual inspection of each and every feedstock container, or

(iii) Each and every feedstock container will be placed inside a water-tight overpack prior to storage, or

(iv) Feedstock containers shall be stored on a hardened surface to prevent spillage onto subsurface soils, and that conforms with the following minimum physical requirements:

A. A storage area composed of a hardened engineered surface of asphalt or concrete, and

B. A storage area designed, constructed, and operated in accordance with engineering plans and specifications approved in advance by the Director. All such engineering plans or specifications submitted shall demonstrate compliance with Part I.D.4 of the GWDP, and

C. A storage area that provides containment berms to control stormwater run-on and run-off, and

D. Stormwater drainage works approved in advance by the Director, or

E. Other storage facilities and means approved in advance by the Director.

Part I.E.7(d) of the GWDP requires that EFRI conduct weekly inspections of all feedstock storage areas to:

(i) Confirm that the bulk feedstock materials are maintained within the approved feedstock storage area specified by Part I.D.3(f) of the GWDP; and

(ii) Verify that all alternate feedstock materials located outside the approved feedstock storage area are stored in accordance with the requirements found in Part I.D.11 of the GWDP.

Part I.E.7(e) further provides that EFRI must conduct weekly inspections to verify that each feed material container complies with the requirements of Part I.D.11 of the GWDP.

The Mill’s procedures for weekly inspection of the ore pad is contained in Section 3.2 of the DMT Plan.

g) Monitor and Maintain Inventory of Chemicals

Part I.D.3(g) of the GWDP requires that for all chemical reagents stored at existing storage facilities and held for use in the milling process, EFRI must provide secondary containment to capture and contain all volumes of reagent(s) that might be released at any individual storage area. Response to spills, cleanup thereof, and required reporting must comply with the provisions of the Mill’s *Emergency Response Plan*, as stipulated by Part I.D.10 of the GWDP. Part I.D.3(g) further provides that for any new construction of reagent storage facilities, such secondary containment and control must prevent any contact of the spilled or otherwise released reagent or product with the ground surface.

Part I.E.9 of the GWDP requires that EFRI must monitor and maintain a current inventory of all chemicals used at the facility at rates equal to or greater than 100 kg/yr. This inventory must be maintained on-site, and must include:

(iii) Identification of chemicals used in the milling process and the on-site laboratory; and

(iv) Determination of volume and mass of each raw chemical currently held in storage at the facility.

2.3.1.5 BAT Performance Standards for Cell 4A

a) BAT Operations and Maintenance Plan

Part I.D.6 and I.D.13 of the GWDP provides that EFRI must operate and maintain Cell 4A and Cell 4B respectively so as to prevent release of wastewater to groundwater and the environment in accordance with the Mill’s Cell 4A BAT Monitoring, Operations and Maintenance Plan. The Mill’s *Cell 4A and 4B BAT Monitoring, Operations and Maintenance Plan*, 07/11 Revision: EFRI 2.3 includes the following performance standards:

(i) The fluid head in the leak detection system shall not exceed 1 foot above the lowest point in the lower membrane liner

(ii) The leak detection system maximum allowable daily leak rate shall not exceed 24,160 gallons/day for Cell 4A and 26,145 gallons/day for Cell 4B

(iii) After EFRI initiates pumping conditions in the slimes drain layer in Cell 4A or Cell 4B, EFRI will provide continuous declining fluid heads in the slimes drain layer, in a manner equivalent to the requirements found in Part I.D.3(b) for Cells 2 and 3

(iv) Under no circumstances shall the freeboard be less than 3-feet in Cell 4B, as measured from the top of the FML

b) Implementation of Monitoring Requirements Under the BAT Operations and Maintenance Plan

The *Cell 4A and 4B BAT Monitoring, Operations and Maintenance Plan* also requires EFRI to perform the following monitoring and recordkeeping requirements:

(i) Weekly Leak Detection System (LDS) Monitoring - including:

A. EFRI must provide continuous operation of the leak detection system pumping and monitoring equipment, including, but not limited to, the submersible pump, pump controller, head monitoring, and flow meter equipment approved by the Director. Failure of any pumping or monitoring equipment not repaired and made fully operational within 24-hours of discovery shall constitute failure of BAT and a violation of the GWDP.

B. EFRI must measure the fluid head above the lowest point on the secondary FML by the use of procedures and equipment approved by the Director. Under no circumstance shall fluid head in the leak detection system sump exceed a 1-foot level above the lowest point in the lower FML, not including the sump.

C. EFRI must measure the volume of all fluids pumped from the leak detection system. Under no circumstances shall the average daily leak detection system flow volume exceed 24,160 gallons/day for Cell 4A or 26,145 for Cell 4B.

D. EFRI must operate and maintain wastewater levels to provide a 3-foot minimum of vertical freeboard in tailings Cell 4B. Such measurement must be made to the nearest 0.1 foot.

(ii) Slimes Drain Recovery Head Monitoring

Immediately after the Mill initiates pumping conditions in the Cell 4A or Cell 4B slimes drain system, quarterly recovery head tests and fluid level measurements will be made in accordance with the requirements of Parts I.D.3(b) and I.E.7(b) of the GWDP and any plan approved by the Director.

2.3.1.6 Stormwater Management and Spill Control Requirements

Part I.D.10 of the GWDP requires that EFRI will manage all contact and non-contact stormwater and control contaminant spills at the facility in accordance with the Mill's stormwater best management practices plan. The Mill's *Stormwater Best Management Practices Plan*, *Revision 1.5* (EFRI, 2016) includes the following provisions:

a) Protect groundwater quality or other waters of the state by design, construction, and/or active operational measures that meet the requirements of the Ground Water Quality Protection Regulations found in UAC R317-6-6.3(G) and R317-6-6.4(C)

b) Prevent, control and contain spills of stored reagents or other chemicals at the Mill site

c) Cleanup spills of stored reagents or other chemicals at the Mill site immediately upon discovery

d) Report reagent spills or other releases at the Mill site to the Director in accordance with UAC 19-5-114

2.3.1.7 Tailings and Slimes Drain Sampling

Part I.E.10 of the GWDP requires that, on an annual basis, EFRI must collect wastewater quality samples from each wastewater source at each tailings cell at the facility, including surface impounded wastewaters, and slimes drain wastewaters, pursuant to the Mill's *Sampling and Analysis Plan for Tailings Cells, Leak Detections Systems and Slimes Drains*, Revision 2.1, July 2012 (the "Tailings Management System SAP"). All such sampling must be conducted in August of each year.

The purpose of the Tailings Management System SAP is to characterize the source term quality of all Mill tailings system wastewaters, including impounded wastewaters or process waters in the Mill tailings system, and wastewater or leachates collected by internal slimes drains. The Tailings Management System SAP requires:

- Collection of samples of the liquid from the tailings management system cells and the slimes drain of each cell that has commenced de-watering activities.
- Samples of liquid and slimes drain material will be analyzed at an offsite contract laboratory and subjected to the analytical parameters included in Table 2 of the GWDP (see Table 2.3-1) and general inorganics listed in Part I.E.1(d)(2)(ii) of the GWDP, as well as semi-volatile organic compounds.
- A detailed description of all sampling methods and sample preservation techniques to be employed.
- The procedures used to analyze these samples will be standard analytical methods used for groundwater sampling as specified in the Mill's QAP.
- The contracted laboratory will be certified by the State of Utah in accordance with UAC R317-6-6.12A.
- 30-day advance notice of each annual sampling event must be given, to allow the DWMRC to collect split samples of all sources.

The tailings management and slimes drain sampling events are subject to the Mill's QAP, unless otherwise specifically modified by the Tailings Management System SAP to meet the specific needs of this type of sampling.

2.3.2 Monitoring and Inspections Required Under the License

2.3.2.1 Environmental Monitoring

The environmental monitoring program is designed to assess the effect of Mill process and disposal operations on the unrestricted environment. Delineation of specific equipment and procedures is presented in the most current version of the Mill's *Environmental Protection Manual*.

c) Ambient Air Monitoring

(i) Ambient Particulate

Airborne radionuclide particulate sampling is performed at seven locations, termed BHV-1, BHV-2, BHV-4, BHV-5, BHV-6, BHV-7, and BHV-8. With the approval of the NRC and effective November 1995, BHV-3 was removed from the active air particulate monitoring program. At that time, the Mill proposed (and NRC determined) that a sufficient air monitoring database had been compiled at station BHV-3 to establish a representative airborne particulate radionuclide background for the Mill. BHV-6 was installed by the Mill at the request of the White Mesa Ute Community. This station began operation in July 1999 and provides airborne particulate information in the southerly direction between the Mill and the White Mesa Ute Community. Figure 2.3-2 shows the locations of these air particulate monitoring stations.

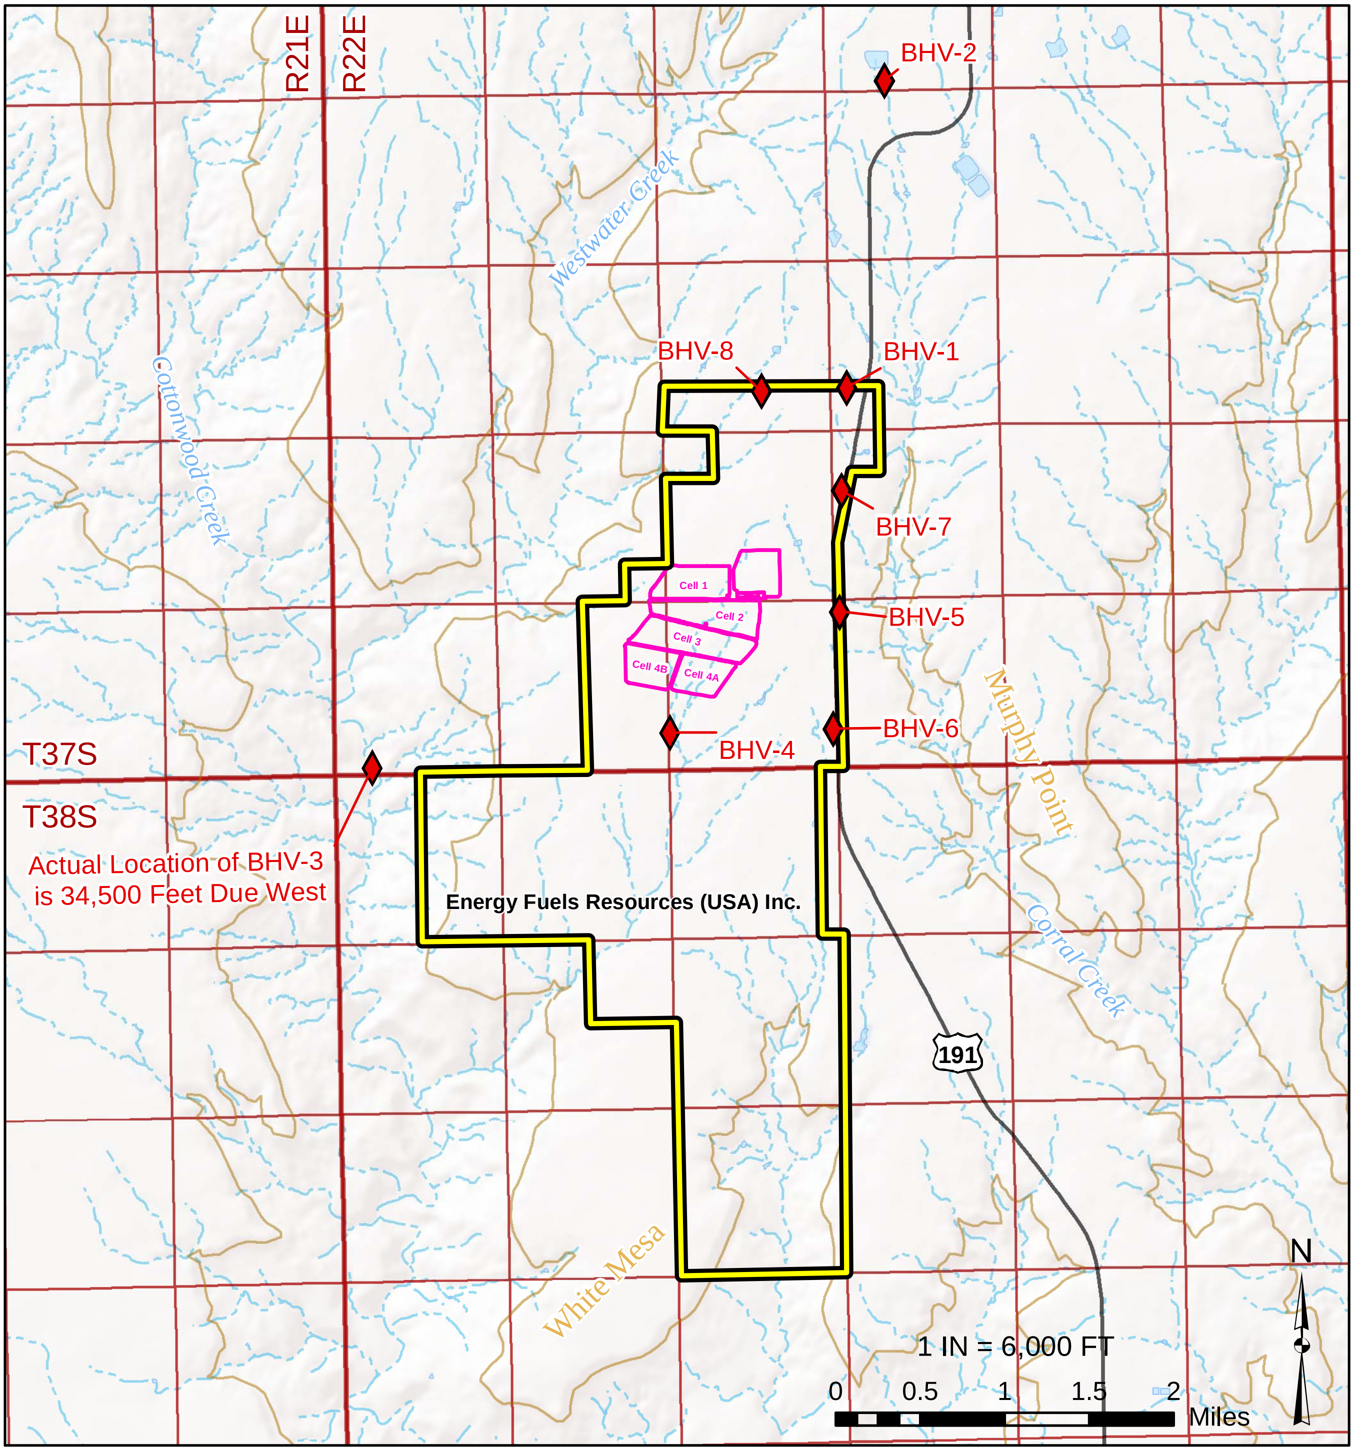
The present sampling system consists of high volume particulate samplers utilizing mass flow controllers to maintain an air flow rate of approximately 32 standard cubic feet per minute. Samplers are operated continuously with a goal for on-stream operating period at ninety percent. Filter replacement is weekly with quarterly site composite for particulate radionuclide analysis. Analysis is done for U-natural, Th-230, Ra-226, Pb-210, and Th-232.

See the current Semi-Annual Effluent Monitoring Report for a summary of monitoring results for airborne particulate.

(ii) Ambient Radon

With the approval of the NRC, Radon-222 monitoring at the BHV stations was discontinued in 1995, due to the unreliability of monitoring equipment available at that time to detect the new 10 CFR standard of 0.1 pCi/l. From that time until the present, the Mill demonstrated compliance with the requirements of R313-15-301 by calculation authorized by the NRC in September 1995 and as contemplated by R313-15-302 (2) (a).

This calculation was performed by use of the MILDOS code for estimating environmental radiation doses for uranium recovery operations (Strenge and Bender 1981) in 1991 in support of the Mill's 1997 license renewal and more recently in 2007 in support of the 2007 License Renewal Application, by use of the updated MILDOS AREA code (Yuan et al., 1998). The analysis under both the MILDOS and MILDOS AREA codes assumed the Mill to be processing high grade Arizona Strip ores at full capacity, and calculated the concentrations of radioactive dust and radon at individual receptor locations around the Mill. Specifically, the modeling under these codes assumed the following conditions:



Legend

- Air Monitoring Station

ENERGY FUELS

REVISIONS		Project: WHITE MESA MILL	
Date:	By:	County: San Juan	State: Utah
		Location: -	
		PARTICULATE MONITORING STATIONS FIGURE 2.3-2	
		Author: areither	Date: 2/13/2015	Drafted By: areither

S:\Source\UT\WhiteMesaMill\Maps\Mill_PartMonitoring.mxd / 2/13/2015 2:35:08 PM by areither

- 730,000 tons of ore per year
- Average grade of 0.53 percent U_3O_8
- Yellowcake production of 4,380 tons of U_3O_8 per year (8.8 million pounds U_3O_8 per year).

Based on these conditions, the MILDOS and MILDOS AREA codes calculated the combined total effective dose equivalent from both air particulate and radon at the current nearest residence (approximately 1.2 miles north of the Mill), i.e., the individual member of the public likely to receive the highest dose from Mill operations, as well as at all other receptor locations, to be below the ALARA goal of 10 mrem/yr for air particulate alone as set out in R313-15-101(4). Mill operations are constantly monitored to ensure that operating conditions do not exceed the conditions assumed in the above calculations. If conditions are within those assumed above, radon has been calculated to be within regulatory limits. If conditions exceed those assumed above, then further evaluation will be performed in order to ensure that doses to the public continue to be within regulatory limits. Mill operations to date have never exceeded the License conditions assumed above.

In order to determine whether or not detection equipment has improved since 1995, EFRI voluntarily began ambient Radon-222 monitoring at the BHV stations in 2013. Radon-222 monitoring is completed using track etch detectors with an effective reporting limit of 0.06 pCi/L. The Radon-222 data collected from 2013 through present are presented in the Semi-Annual Effluent Monitoring Reports. Amendment 7 of the Mill Radioactive Materials License expanded the Mill's effluent monitoring programs in 2014. Amendment 7 included expanding the monitoring programs to require the collection of Radon-222 data at all of the BHV stations.

d) External Radiation

Optically Stimulated Luminescence ("OSL") badges, as supplied by Landauer, Inc., or equivalent, are utilized at all of the high volume air monitoring stations to determine ambient external gamma exposures (see Figure 2.3-2). System quality assurances are determined by placing a duplicate monitor at one site continuously. Exchanges of OSL badges are on a quarterly basis. Measurements obtained from location BHV-3 have been designated as background due to BHV-3's remoteness from the Mill site (BHV-3 is located approximately 3.5 miles west of the Mill site). For further procedural information see Section 4.3 of the most recent version of the Mill's *Environmental Protection Manual*. See the current Semi-Annual Effluent Monitoring Report for a summary monitoring results for external radiation.

e) Soil and Vegetation

(i) Soil Monitoring

As mentioned above, specific changes to the individual monitoring programs, including the soil sampling program, has been made as a result of Amendment 7 to the Radioactive Materials License.

Soil samples from the top 2 inches of surface soils are collected annually at each of the 52 locations (see Figure 2.3-3). and the soil samples are analyzed for U-natural, Ra-226, Pb-210, and Th-232. For further procedural information see Section 4.1 of the most current version of the Mill's *Environmental Protection Manual*. See Section 3.13.1.7.1 of the 2007 ER and the current Semi-Annual Effluent Monitoring Report for a summary of the historic results for soil monitoring. The 2007 ER concludes that the results of sampling are low, less than the unrestricted release limits.

S:\Source\UT\WhiteMesaMill\Maps\SoilMonitoringLocations.mxd / 2/16/2016 2:03:08 PM by areither

(ii) Vegetation Monitoring

Forage vegetation samples are collected three times per year from animal grazing locations to the northeast (near BHV-l (the meteorological station)), northwest (to the immediate west of the site) and southwest (by BHV-4) of the Mill site. Samples are obtained during the grazing season, in the late fall, early spring, and in late spring. A minimum of three kilograms of vegetation are submitted from each site for analysis of U-natural, Ra-226, Pb-210, and Th-232. For further procedure information see Section 4.2 of the most current version of the Mill's *Environmental Protection Manual*. See Section 3.13.7(d) of the 2007 ER and the current Semi-Annual Effluent Monitoring Report for a summary of the historic results for vegetation monitoring. The most recent results indicate no increase in uptake of U-natural, Ra-226 Th-232, and Pb-210 in vegetation.

d) Meteorological

Meteorological monitoring is performed at a site near BHV-1. The sensor and recording equipment are capable of monitoring wind velocity and direction, from which the stability classification is calculated. Data integration duration is one-hour with hourly recording of mean speed, mean wind direction, and mean wind stability (as degrees sigma theta).

The data from the meteorological station is retrieved monthly by down loading onto a Campbell Scientific data module, or the equivalent. The data module is sent to an independent meteorological contractor where the module is downloaded to a computer record, and the data is correlated and presented in a Semi-Annual Meteorological Report.

Monitoring for precipitation consists of a daily log of precipitation using a standard NOAA rain gauge, or the equivalent, installed near the administrative office, consistent with NOAA specifications.

Windrose data is summarized in a format compatible with MILDOS and UDAD specifications for 40 CFR 190 compliance. For further procedural information see Section 1.3 of the most current version of the Mill's *Environmental Protection Manual*. A windrose for the site is set out in Figure 1.1-1.

e) Point Emissions

Stack emission monitoring from yellowcake facilities follows EPA Method 5 procedures and occurs on the following schedule shown in Table 2.3-2.

Table 2.3-2
Stack Sampling Requirements

Frequency	Grizzly Baghouse Stack	North and/or South Yellowcake Dryer Stacks	Yellowcake Packaging Baghouse Stack	Vanadium Dryer Stack	Vanadium Packaging Stack
Quarterly	If operating, U-nat, Th-230, Ra-226, Pb-210, Th-232, Ra-228, and Th-228.	If operating, U-nat, Th-230, Ra-226, Pb-210, Th-232, Ra-228, and Th-228.	If operating, U-nat, Th-230, Ra-226, Pb-210, Th-232, Ra-228, and Th-228.	If operating, U-nat, Th-230, Ra-226, Pb-210, Th-232, Ra-228, and Th-228.	If operating, U-nat, Th-230, Ra-226, Pb-210, Th-232, Ra-228, and Th-228.

Monitored data includes scrubber system operation levels, process feed levels, particulate emission concentrations, isokinetic conditions, and radionuclide emission concentrations. For further procedure information see Section 1.4 of the most current version of the Mill's *Environmental Protection Manual*. Stack emission data are summarized in the Semi-Annual Effluent Monitoring Report.

f) Surface Water Monitoring

Surface water monitoring is conducted at two locations adjacent to the Mill facility known as Westwater Canyon and Cottonwood Creek. Grab samples are obtained annually from Westwater and quarterly from Cottonwood. For Westwater Creek, samples of sediments will be collected if a water sample is not available. Field monitored parameters and laboratory monitored parameters are listed in Table 2.3-3. For further procedural information see Section 2.1 of the most current version of the Mill's *Environmental Protection Manual*. See the current Semi-Annual Effluent Monitoring Report for a summary monitoring results for surface water.

2.3.2.2 Additional Monitoring and Inspections Required Under the License

Under the License daily, weekly, and monthly inspection reporting and monitoring are required by NRC Regulatory Guide 8.31, *Information Relevant to Ensuring that Occupational Radiation Exposures at Uranium Recovery Facilities will be As Low As is Reasonable Achievable*, Revision 1, May 2002 ("Reg Guide 8.31"), by Section 2.3 of the Mill's ALARA Program and by the DMT Plan, over and above the inspections described above that are required under the GWDP. A copy of the Mill's ALARA Program is included as Appendix I to the 2007 License Renewal Application.

a) Daily Inspections

Three types of daily inspections are performed at the Mill under the License:

(i) Radiation Staff Inspections

Paragraph 2.3.1 of Reg. Guide 8.31 provides that the Mill's Radiation Safety Officer ("RSO") or designated health physics technician should conduct a daily walk-through (visual) inspection of all work and storage areas of the Mill to ensure proper implementation of good radiation safety procedures, including good housekeeping that would minimize unnecessary contamination. These inspections are required by Section 2.3.1 of the Mill's ALARA Program, and are documented and on file in the Mill's Radiation Protection Office.

(ii) Operating Foreman Inspections

30 CFR Section 56.18002 of the Mine Safety and Health Administration regulations requires that a competent person designated by the operator must examine each working place at least once each shift for conditions which may adversely affect safety or health. These daily inspections are documented and on file in the Mill's Radiation Protection Office.

(iii) Daily Tailings Inspection

Section 2 of the DMT Plan requires that during Mill operation, the Shift Foreman, or other person with the training specified in Appendix B of the Tailings Management System, designated by the RSO, will perform an inspection of the tailings line and tailings area at least once per shift, paying close attention for potential leaks and to the discharges from the pipelines. Observations by the Inspector are recorded on the appropriate line on the Mill's Daily Inspection Data form.

b) Weekly Inspections

Three types of weekly inspections are performed at the Mill under the License:

(i) Weekly Inspection of the Mill Forms

Paragraph 2.3.1 of Reg. Guide 8.31 provides that the RSO and the Mill foreman should, and Section 2.3.2 of the Mill's ALARA Program provides that the RSO and Mill foreman, or their respective designees, shall conduct a weekly inspection of all Mill areas to observe general radiation control practices and review required changes in procedures and equipment. Particular attention is to be focused on areas where potential exposures to personnel might exist and in areas of operation or locations where contamination is evident.

(ii) Weekly Ore Storage Pad Inspection Forms

Section 3 of the DMT Plan requires that weekly feedstock storage area inspections will be performed by the Radiation Safety Department, to confirm that the bulk feedstock materials are stored and maintained within the defined area of the ore pad and that all alternate feed materials located outside the defined ore pad area are maintained within water tight containers. The results of these inspections are recorded on the Mill's Ore Storage/Sample Plant Weekly Inspection Report.

(iii) Weekly Tailings and DMT Inspection

Section 3 of the DMT Plan require that weekly inspections of the tailings area and DMT requirements be performed by the radiation safety department.

c) Monthly Reports

Two types of monthly reports are prepared by Mill staff:

(i) Monthly Radiation Safety Reports

At least monthly, the RSO reviews the results of daily and weekly inspections, including a review of all monitoring and exposure data for the month and provides to the Mill Manager a monthly report containing a written summary of the month's significant worker protection activities (Section 2.3.4 of the Mill's ALARA Program).

(ii) Monthly Tailings Inspection Reports

The Tailings Management System Plan requires that a Monthly Inspection Data form be completed for the monthly tailings inspection. This inspection is typically performed in the fourth week of each month and is in lieu of the weekly tailings inspection for that week.

Mill staff also prepares a monthly summary of all daily, weekly, monthly and quarterly tailings inspections.

d) Quarterly Tailings Inspections

The Tailings Management System Plan requires that the RSO or his designee perform a quarterly tailings inspection.

e) Annual Evaluations

The following annual evaluations are performed under the License, as set out in Section 6 of the Tailings Management System Plan.

(i) Annual Technical Evaluation

An annual technical evaluation of the tailings management system must be performed by a registered professional engineer (PE), who has experience and training in the area of geotechnical aspects of retention structures. The technical evaluation includes an on-site inspection of the tailings management system and a thorough review of all tailings records for the past year. The Technical Evaluation also includes a review and summary of the annual movement monitor survey (see paragraph (ii) below).

All tailings management system components and corresponding dikes are inspected for signs of erosion, subsidence, shrinkage, and seepage. The drainage ditches are inspected to evaluate surface water control structures.

In the event tailings capacity evaluations were performed for the receipt of alternate feed material during the year, the capacity evaluation forms and associated calculation sheets will be reviewed to ensure that the maximum tailings capacity estimate is accurate. The amount of tailings added to the system since the last evaluation will also be calculated to determine the estimated capacity at the time of the evaluation.

As discussed above, tailings inspection records consist of daily, weekly, monthly, and quarterly tailings inspections. These inspection records are evaluated to determine if any freeboard limits are being approached. Records will also be reviewed to summarize observations of potential concern. The evaluation also involves discussion with the Environmental and/or Radiation Technician and the RSO regarding activities around the tailings area for the past year. During the annual inspection, photographs of the tailings area are taken. The training of individuals is also reviewed as a part of the Annual Technical Evaluation.

The registered engineer obtains copies of selected tailings inspections, along with the monthly and quarterly summaries of observations of concern and the corrective actions taken. These copies are then included in the *Annual Technical Evaluation Report*.

The *Annual Technical Evaluation Report* must be submitted by November 15th of every year to the Director and to the Directing Dam Safety Engineer, State of Utah, Natural Resources.

(ii) Annual Movement Monitor Survey

A movement monitor survey is conducted by a licensed surveyor semi-annually for the first three years, and annually thereafter during the second quarter of each year. The movement monitor survey consists of surveying monitors along dikes 4A-W, 4A-S and 4B-S to detect any possible settlement or movement of the dikes. The data generated from this survey is reviewed and incorporated into the *Annual Technical Evaluation Report* of the tailings management system.

(iii) Annual Leak Detection Fluid Samples

In the event solution has been detected in a leak detection system in Cells 1, 2 or 3, a sample will be collected on an annual basis. This sample will be analyzed according to the conditions set forth in License Condition 11.3.C. The results of the analysis will be reviewed to determine the origin of the solution.

3 TAILINGS RECLAMATION PLAN

This section provides an overview of the Mill location and property; details the facilities to be reclaimed; and describes the design criteria applied in this Plan. Drawings are presented as an attachment to this report. Technical specifications are presented in Attachment A. Attachment B presents the quality assurance and quality control plan for construction activities. Attachment C presents cost estimates for reclamation (based on the Existing Cover Design). Attachment D presents the most current Radiation Protection Manual for Reclamation Activities. Attachment E provides documents on the approved Existing Cover Design that was presented in Reclamation Plan Revision 3.2b (Denison, 2011b).

The Reclamation Plan is written assuming the tailings management system Cells 2, 3, 4A, and 4B will receive tailings to the maximum permitted tailings elevations. Cell 4B is used for evaporation of process solutions and has not been used for tailings storage. The Plan has been written assuming Cell 4B will be used in the future for tailings storage.

If Cell 4B is not used in the future for tailings storage, Cell 4B can be reclaimed for clean closure. Any remaining solutions would be pumped to the last active tailings Cell. The liner system would be removed and disposed in the last active tailings cell. The exterior embankments would then be regraded. This design is not presented in this report.

3.1 Location and Property Description

The Mill is located approximately six miles south of Blanding, Utah on US Highway 191 on a parcel of land encompassing all or part of Sections 21, 22, 27, 28, 29, 32, and 33 of T37S, R22E, and Sections 4, 5, 6, 8, 9, and 16 of T38S, R22E, Salt Lake Base and Meridian described as follows (Figure 3.1-1):

> The south half of the south half of Section 21; the southeast quarter of the southeast quarter of Section 22; the northwest quarter of the northwest quarter and lots 1 and 4 of Section 27 all that part of the southwest quarter of the northwest quarter and the northwest quarter southwest quarter of Section 27 lying west of Utah State Highway 163; the northeast quarter of the northwest quarter, the south half of the northwest quarter, the northeast quarter and the south half of Section 28; the southeast quarter of the southeast quarter of Section 29; the east half of Section 32 and all of Section 33, Township 37 South, Range 22 East, Salt Lake Base and Meridian. Lots 1 through 4, inclusive, the south half of the north half, the southwest quarter, the west half of the southeast quarter, the west half of the east half of the southeast quarter and the west half of the east half of the east half of the southeast quarter of Section 4; Lots 1 through 4, inclusive, the south half of the north half and the south half of Section 5 (all); Lots 1 and 2, the south half of

Additional land is controlled by 46 Mill site claims. Total land holdings are approximately 5,415 acres.

3.2 Facilities to be Reclaimed

See the Drawings for a general layout of the Mill yard and related facilities and the restricted area boundary.

3.2.1 Summary of Facilities to be Reclaimed

The facilities to be reclaimed include the following:

- Cell 1 (evaporation). Cell 1 was previously referred to as Cell 1-I.
- Cells 2, 3, and 4A (tailings).
- Cell 4B (This cell is currently used for evaporation. The reclamation design assumes this cell will be used for tailings in the future).
- Mill buildings and equipment.
- On-site contaminated areas.
- Off-site contaminated areas (i.e., potential areas affected by windblown tailings).

The reclamation of the above facilities will include the following:

- Placement of contaminated soils, crystals, and synthetic liner material and any contaminated underlying soils from Cell 1 into the last active tailings cell
- Placement of a liner system on a portion of the Cell 1 impoundment area to be used for disposal of contaminated materials and debris from the Mill site, if needed
- Decommissioning Cell 1
- Placement of materials and debris from Mill decommissioning into the last active tailings cell or Cell 1 Disposal Area
- Placement of an engineered multi-layer cover over the entire area of Cells 2, 3, 4A, 4B, and the Cell 1 Disposal Area
- Construction of runoff control and diversion channels as necessary
- Reclamation of Mill and ancillary areas
- Reclamation of borrow sources

3.2.2 Tailings and Evaporative Cells

The following subsections describe the cover design and reclamation procedures for Cells 1, 2, 3, 4A, and 4B. Complete engineering details and text are presented in the Updated Tailings Cover Design Report included as Appendix A to this Reclamation Plan.

Cell 2 final cover construction will take place before final cover construction on other cells at the White Mesa Mill. Cell 2 final cover construction will occur in two phases and includes a performance monitoring test section (Primary Test Section) containing a lysimeter constructed in the southeast portion of Cell 2 concurrently with the Phase 1 cover placement. A Supplemental Test Section has been constructed north of the tailings management cells relating to vegetative cover and erosion control. The plan for implementing final cover placement on Cell 2 and performance assessment and monitoring is presented in Appendix A. Cell 2 Phase 1 cover placement began in May 2016 and was completed in 2017. The Primary Test Section was constructed in the fall of 2016. The Supplemental Test Section was constructed in the fall of 2017.

3.2.2.1 Soil Cover Design

A conceptual ET cover design was proposed by EFRI for the White Mesa Mill tailings management cells in the Infiltration and Contaminant Transport Modeling (ICTM) reports (MWH 2007 and 2010) submitted to the DWMRC to fulfill the White Mesa Mill's Ground Water Discharge Permit No. UGW370004.

EFRI stated their intent to submit an ET cover design as part of their license renewal in a meeting with DWMRC on October 5, 2010 after review of the DWMRC Reclamation Plan, Version 4.0 Interrogatories – Round 1 (DRC, 2010). The proposed conceptual ET cover design was provided to DWMRC on October 7, 2010 and was essentially the same as presented in the 2010 Infiltration and Contaminant Transport Model report (MWH, 2010). The ET cover proposed and evaluated as described in the Updated Tailings Cover Design Report (Appendix A) is designed as 9.5 feet thick for Cells 1, 4A, and 4B, 10 feet thick for Cell 3, and 10.5 feet thick for Cell 2. The difference in cover thickensses is based on radon emanation analyses. The cover system consists of the following materials outlined below by individual layers and thicknesses from top to bottom:

- Layer 4 - 0.5 ft (15 cm) thick Erosion Protection Layer (gravel-admixture or topsoil)
- Layer 3 - 3.5 ft (107 cm) thick Growth Medium Layer acting as a Water Storage/Biointrusion/Frost Protection/Secondary Radon Attenuation Layer (loam to sandy clay)
- Layer 2 – 3.0 to 4.0 ft (91 to 122 cm) thick Compacted Cover acting as the Primary Radon Attenuation Layer (highly compacted loam to sandy clay)
- Layer 1 - 2.5 ft (76 cm) thick (minimum) Interim Fill Layer acting as a Secondary Radon Attenuation and Grading Layer (loam to sandy clay)

All the layers combined comprise the monolithic ET cover system. Layer 1 was placed in stages on Cell 2 and the majority of Cell 3 as interim cover. Layer 1 will be placed on the remaining area of Cell 3, all of the Cell 1 Disposal Area, and Cells 4A and 4B. It is assumed that this material was or will be dumped and minimally compacted by construction equipment to approximately 80 percent of standard Proctor density. Layer 1 will provide the platform for the remaining cover system and act as a secondary radon attenuation layer. Layer 2 will be compacted cover layer and act as the primary radon attenuation layer. It will be 3 - 4 feet thick (3 feet for Cells 1, 4A, and 4B, 3.5 feet for Cell 3, and 4 feet for Cell 2) and compacted to 95 percent of standard Proctor density. Layer 3 will be the growth medium layer. Layer 3 will also act as a secondary radon attenuation layer and a protection layer for the primary radon attenuation layer (Layer 2). Layer 3 will be 3.5 feet thick and placed at 85 percent of standard Proctor density to optimize water storage and rooting characteristics for plant growth. Layer 4 will be a 0.5-foot thick erosion protection layer. This layer will consist of topsoil in areas where the cover is sloped at 0.5 percent and topsoil-gravel admixture in areas where the cover is sloped at 1 percent. The topsoil-gravel admixture will consist of topsoil (75 percent) mixed with 1-inch minus gravel (25 percent).

The majority of the cover will be constructed from materials available from within the site boundaries. As a part of the soil cover, erosion protection will be placed as the top layer of the cover to stabilize slopes and provide long-term erosion resistance (see Appendix A for characterization of cover materials). The erosion protection materials will be obtained from off-site sources.

The key state and federal performance criteria for tailings cover design and reclamation include:

- Attenuate radon flux to a rate of 20 pCi/m2-s, averaged over each entire cell
- Minimize infiltration into the reclaimed tailings cells
- Maintain a design life of up to 1,000 years and at least 200 years
- Provide long-term isolation of the tailings, including slope stability and geomorphic durability to withstand erosional forces of wind and runoff (up to the probable maximum precipitation event) as well as design to accommodate seismic events (up to the peak ground acceleration from the maximum credible earthquake)
- Designs to accommodate minimum reliance on active maintenance

Several models/analyses were utilized in simulating the soil cover effectiveness: radon flux attenuation, infiltration, freeze/thaw effects, erosion protection, static and pseudostatic slope stability analyses, biointrusion, tailings dewatering, liquefaction, and settlement. These analyses and results are discussed in detail in Sections 3.3.2 through 3.3.10, and calculations are also shown in the Updated Tailings Cover Design Report (Appendix A).

The final grading plans are presented in the Drawings. As indicated in the Drawings, the drainage on the top surface of the ET cover at Cells 1, 2, and 3 is designed at a 0.5 percent slope, with portions of Cell 2 top surface at a 1 percent slope and portions of Cells 4A and 4B top surfaces at 0.8 percent slope. The external side slopes will be graded to five horizontal to one vertical (5H:1V).

3.2.2.2 Cell 1

Cell 1, used during Mill operations solely for evaporation of process liquids, is the northernmost existing cell and is located immediately west of the Mill. It is also the highest cell in elevation, as the natural topography slopes to the south. The drainage area above and including the cell is 216 acres. This includes drainage from the Mill site.

Cell 1 will be evaporated to dryness. The synthetic liner and raffinate crystals will then be removed and placed in the tailings cells. Any contaminated soils below the liner will be removed and also placed in the tailings cells. Based on current regulatory criteria, the current plan calls for excavation of the residual radioactive materials to be designed to ensure that the concentration of radium-226 in land averaged over any area of 100 square meters does not exceed the background level by more than:

- 5 pCi/g, averaged over the first 15 cm of soil below the surface
- 15 pCi/g, averaged over a 15 cm thick layer of soil more than 15 cm below the surface

A portion of Cell 1 (i.e., the Cell 1 Disposal Area), adjacent to and running parallel to the downstream cell dike, may be used for permanent disposal of contaminated materials and debris from the Mill site decommissioning and windblown cleanup. The actual area of the Cell 1 Disposal Area needed for storage of additional material will depend on the status of Cells 3, 4A, and 4B at the time of final Mill decommissioning. A portion of the Mill area decommissioning material may be placed in Cells 3, 4A or 4B if space is available, but for purposes of the reclamation design the entire quantity of contaminated materials from the Mill site decommissioning is assumed to be placed in the Cell 1 Disposal Area, which will subsequently be covered with the ET cover. This results in approximately 10 acres of the Cell 1 area constituting the Cell 1 Disposal Area and being utilized for permanent tailings storage. The remaining area of Cell 1 will then be breached and converted to a sedimentation basin. All runoff from the covered Cell 1 Disposal Area, the Mill area and the area immediately north of Cell 1 will be routed into the sedimentation basin and will discharge onto the natural ground via the channel located at the southwest corner of the basin. The channel is designed to accommodate the PMF flood. Hydraulic and erosional analyses are provided in Appendix A. The channel will be a bedrock channel with a 0.1 percent channel slope, 150-foot bottom width, and 3 horizontal: 1 vertical sideslopes.

3.2.2.3 Cell 2

Cell 2 has been filled with tailings and will be covered with the ET cover to a minimum cover thickness of 10.5 feet. The final cover will drain at a slope of 0.5 to 1 percent to the north and south as shown in the Drawings.

The cover will be as described in Section 3.2.2.1 above and will consist of a 2.5 feet of interim fill, followed by 4 feet of compacted cover, overlain by 3.5 feet of growth medium. Half a foot of topsoil or gravel-admixture will be utilized as armor against erosion at the surface of the cover. External side slopes will be graded to a 5:1 slope and will have 6 inches of angular riprap on the cover surface for erosion protection. A rock apron with dimensions as shown in the Drawings will be constructed at the transition areas of the toes of the side slopes of Cell 2.

3.2.2.4 Cell 3

Cell 3 will be filled with tailings, debris and contaminated soils and covered with the same ET cover system and erosion protection as Cell 2, except the total thickness will be 10 feet with a compacted cover layer of 3.5 feet.

3.2.2.5 Cells 4A and 4B

Cells 4A and 4B are designed to be filled with tailings, debris and contaminated soils and will be covered with the same ET cover system as Cell 2 and Cell 3, except the total thickness will be 9.5 feet with a compacted cover layer of 3 feet. The south external side slopes will be graded to 5H:1V and will have 8 inches of angular riprap on the cover surface for erosion protection. A rock apron with dimensions as shown on the drawings will be constructed at the south side slopes of Cells 4A and 4B. The east and west external side slopes will be graded to 5H:1V and have the same erosion protection as the east and west sides slopes of Cells 2 and 3.

3.3 <u>Design Criteria</u>

As required by Part I.H.11 of the GWDP, EFRI has completed an infiltration and contaminant transport model of the final tailings cover system to demonstrate the long-term ability of the ET cover to protect nearby groundwater quality. The ET cover design and basis presented in Appendix A will be used for this version of the Plan.

The design criteria summaries in this section are adapted from the Updated Tailings Cover Design Report. A copy of the Tailings Cover Design Report is included as Appendix A. It contains all of the calculations used in design and summarized in this section.

3.3.1 Regulatory Criteria

Information contained in 10 CFR Part 20, 10 CFR Part 40 and Appendix A to 10 CFR Part 40 (which are incorporated by reference into UAC R313-24-4), and 40 CFR Part 192 were used as criteria in final designs under this Plan. In addition, the following documents also provided guidance:

- Benson, C.H. W.H. Albright, D.O. Fratta, J.M. Tinjum, E. Kucukkirca, S.H. Lee, J. Scalia, P.D. Schlicht, and X. Wang, 2011. Engineered Covers for Waste Containment: Changes in Engineering Properties and Implications for Long-Term Performance Assessment (in four volumes). - U.S. Nuclear Regulatory Commission (NRC), 1990. "Final Staff Technical Position, Design of Erosion Protective Covers for Stabilization of Uranium Mill Tailings Sites," August.
- U.S. Nuclear Regulatory Commission (NRC), 2003. Standard Review Plan for the Review of a Reclamation Plan for Mill Tailings Sites under Title II of the Uranium Mill Tailings Radiation Control Act of 1978. NUREG-1620, Revision 1, June.

As mentioned above, the requirements set out in Part I.D.8 of the GWDP require that the cover system for each tailings cell will be designed and constructed to meet the following minimum performance requirements for a period of not less than 200 years:

- Minimize the infiltration of precipitation or other surface water into the tailings, including, but not limited to the radon barrier

- Prevent the accumulation of leachate head within the tailings waste layer that could rise above or over-top the maximum FML elevation internal to any disposal cell, i.e. create a "bathtub" effect
- Ensure that groundwater quality at the compliance monitoring wells does not exceed the GWQSs or GWCLs specified in Part I.C.1 and Table 2 of the GWDP

3.3.2 Radon Flux Attenuation

Analyses of radon attenuation through the monolithic ET cover have been performed, and incorporate the current cover design, final grading plan, and results of geotechnical testing of material properties. Emanation of radon-222 from the top surface of the proposed cover system for the tailings cells was calculated using the NRC RADON model (NRC, 1989). The model was used to confirm that the designed cover system can achieve the State of Utah's long-term radon emanation standard for uranium mill tailings (Utah Administrative Code, Rule 313-24), 20 picocuries per square meter per second (pCi/m^2-s). The analyses were conducted following the guidance presented in NRC publications NUREG/CR-3533 (NRC, 1984) and Regulatory Guide 3.64 (NRC, 1989). Results of the analyses show that the proposed cover system can reduce the rate of radon-222 emanation to less than 20 pCi/m^2-s, averaged over the entire area of each tailings cell. A complete description of the radon attenuation analyses conducted for the ET cover system is included in Appendix A.

3.3.3 Infiltration Analysis

Infiltration modeling was conducted for the monolithic ET cover and a complete description of the analyses were provided in the ICTM Report (MWH, 2010). The modeling was updated to address DWMRC comments on the ICTM Report (DRC, 2012; 2013) and to incorporate additional geotechnical and hydrologic data collected in as part of field investigations conducted in 2010 and 2012 for cover borrow material and in 2013 for in situ tailings. The updated infiltration modeling results were presented in EFRI (2012b) and EFRI (2015c). The evaluation of infiltration of precipitation through the cover system was evaluated with the computer program HYDRUS-1D (Simunek et al., 2009). The modeling used historical daily meteorological data for precipitation and evapotranspiration over a 57-year climate period, as well as assumptions that were either conservative or based on anticipated conditions. Given the flat nature of the cover (less than 1 percent slope), no run-on- or runoff-based processes were assumed to occur. As a result, precipitation applied to the cover surface was removed through evaporation or transpiration, retained in the soil profile as storage, or transmitted downward as infiltration.

The model-predicted average long-term water flux rate through the cover system is 2.3 mm/yr. Additional model scenarios were analyzed to evaluate the sensitivity of the soil properties, climate, and reduced vegetation parameters. The range of average long-term water flux rates for these scenarios varied from 1.9 to 8.6 mm/yr. The model-predicted water flux rates through the monolithic ET cover indicate that the available cover storage capacity should be sufficient to significantly reduce infiltration through the cover system. A complete description of the infiltration analyses conducted for the monolithic ET cover is provided in MWH (2010) with updates provided in EFRI (2012b, 2015c), and is summarized in Appendix A to this Reclamation Plan.

3.3.4 Freeze/Thaw Evaluation

A freeze/thaw analysis was performed for the monolithic ET cover system, utilizing geotechnical properties of materials specified for use in construction of the cover. The calculations of frost penetration at the site were performed with the computer program ModBerg (CRREL), which uses a built-in weather database, as well as user-defined soil parameters.

The freeze/thaw calculations estimate the total depth of frost penetration for the cover system as 32 inches (2.67 ft). The frost penetration depth is not anticipated to exceed the depth of Layers 3 and 4 of the cover system (combined depth of 4 ft). The physical and hydraulic properties of these cover system layers after construction are expected to be close to long-term properties from pedogenic processes, such that post-construction changes due to freeze/thaw should be minimal. A complete description of the freeze/thaw analyses conducted for the proposed cover system is presented in the Updated Tailings Cover Design Report, attached as Appendix A to this Reclamation Plan.

3.3.5 Soil Cover Erosion Protection

The erosional stability of the reclaimed tailings cells was evaluated in terms of long-term water erosion under extreme storm conditions. The analyses were conducted in general accordance with NRC guidelines (NRC, 1990; Johnson, 2002). A description of the analyses performed is presented in Appendix A.

The components of erosion protection for the reclaimed tailings cells consist of the following:

- The cover on the top surface of Cells 1, 2, and 3, with slopes of 0.5 percent, would be constructed as a vegetated slope, with 6 inches of topsoil.
- The portions of Cell 2 with a top surface of 1 percent slope, and the portions of Cells 4A and 4B with 0.8 percent slope, would be constructed as a vegetated slope with 6 inches of topsoil mixed with 25 percent (by weight) gravel (maximum diameter of 1 inch).
- Erosion protection of external (5H:1V) side slopes would be provided by various sized angular and rounded riprap with layer thicknesses ranging from 6 to 8 inches and median particle sizes ranging from 1.7 to 5.3 inches. A 6-inch layer of filter material would be placed between the erosional protection layer and underlying soil layer in locations with riprap greater than 1.7 inches. A narrow zone of this filter will also be placed at the interface between the riprap (greater than 1.7 inches) on the external side slopes and the cover surface erosion protection layer.
- The toe of embankment slopes will have erosional protection and scour protection on the west and east sides of the cells provided by a rock apron measuring approximately 10 inches deep and 5 feet wide, with a median particle size of 3.4 inches. On the south side of cells 4A and 4B, and east side of Cell 4A, the rock apron would be approximately 3 feet in depth, 13 feet in width, and have a median particle size of 10.6 inches. On the north side slope of the Cell 1 disposal area, the rock apron would be approximately 3 feet deep, 11 feet wide, and have a median particle size of 9 inches.
- The Sedimentation Basin area will be graded to 0.1 percent slope and constructed as a vegetated slope with 6 inches of topsoil.
- The Diversion Channel will be excavated into bedrock.

3.3.6 Slope Stability Analysis

Static (long-term) and pseudo-static slope stability analyses were performed for two critical cross sections through the tailings embankments. The analyses were performed using limit equilibrium methods with the computer program SLOPE/W (Geo-Slope, 2007). A complete description of the input parameters and assumptions used in the analyses is provided in Appendix A. Material strength parameters used for the analyses were based on historical laboratory testing on tailings and clay materials (Advanced Terra Testing, 1996; Chen and Associates, 1987; D'Appolonia, 1982; and Western Colorado Testing, 1999), laboratory testing conducted in 2010 and 2012 on potential cover borrow materials (see Attachment B of EFRI, 2012a), laboratory testing conducted in 2013 on tailings (MWH, 2015b) and typical published values.

The mean Peak Ground Acceleration (PGA) for reclaimed conditions is 0.15g based on the site specific PSHA (MWH, 2015a). This PGA represents the seismic loading from the Maximum Credible Earthquake (MCE). The seismic coefficient used for the pseudo static stability analysis was 0.10 g (equal to 2/3 of the PGA).

The calculated factors of safety range from 2.6 to 3.9 and 1.7 to 2.5 for static and pseudo-static loading conditions, respectively. The calculated factors of safety for both the long-term static condition and the pseudo-static condition exceed the required values of 1.5 and 1.1 respectively (NRC, 2003).

3.3.7 Tailings Dewatering

Cells 2, 3, 4A, and 4B are constructed to allow tailings dewatering. Dewatering analyses have been conducted for these tailings management cells assuming the cells receive tailings to the maximum permitted tailings elevation. Dewatering analyses for Cells 2 and 3 were conducted by MWH and are presented in Appendix A. Dewatering analyses for Cells 4A and 4B were conducted by Geosyntec (2007a, 2007b). The pertinent excerpts from MWH (2010), Geosyntec (2007a, 2007b), and DRC (2008) are included in Appendix A.

Water levels in Cells 2 and 3 were measured during the October 2013 tailings investigation (MWH, 2015b). Results of the investigation indicated migration of water towards the sump in Cell 2. This was expected since water has been pumped from the Cell 2 sump since 2008. Dewatering of Cell 3 has not yet started and the October 2013 investigation reflected this, with measured water levels a few feet below the tailings surface.

To monitor changes in water levels due to dewatering prior to and after final cover placement, installation of standpipe piezometers was recommended across the cells prior to the first phase of final cover placement and extension of the piezometers during final cover placement. These piezometers will provide information on the rate and extent of dewatering of the tailings. The piezometers are primarily located adjacent to the settlement monuments to minimize damage to the piezometers during cover construction, while providing sufficient locations to evaluate the water levels. Water levels are recommended to be monitored at the same frequency and duration as the settlement monuments. Piezometer locations for Cell 2 are shown in Appendix L of the Updated Tailings Cover Design Report.

3.3.8 Settlement and Liquefaction Analyses

Settlement analyses and evaluation of liquefaction potential for the tailings were performed for the tailings cells. A discussion of the analyses and results are provided in Appendix A.

One-dimensional settlement analyses were conducted to evaluate settlement due to placement of final cover, dewatering of the tailings cells, long-term static (creep) settlement, and seismically induced (seismic) settlement. The results of these analyses of specific locations were used to evaluate differential settlement and the potential for cover cracking. The CPT locations in Cell 2 and 3 from the October 2013 tailings investigation (MWH, 2015b) were selected as the locations for the settlement analyses. Parameters used for the settlement analyses are summarized in Appendix A. Tailings profiles and properties are based on results presented in MWH (2015a). Parameters for cover materials are based on cover material testing conducted in 2010 and 2012 (summarized in Appendix A). Evaluation of total settlement due to final cover placement and dewatering indicates potential future settlement during active maintenance ranging from 0.9 to 1.6 feet.

The majority of this settlement is expected occur after Phase 1 cover construction with the remaining settlement occurring soon after Phase 2 cover construction. During this time, additional fill may be placed in low areas to maintain positive drainage of the cover surface. The estimated total predicted future long-term settlement that could occur (due to creep and seismic settlement) after the maintenance period is complete ranges from approximately 0.3 to 0.7 feet. Estimates of total long-term settlement were calculated by summing the static creep and seismic settlement estimates. As such, these estimates are considered somewhat conservative, as they are not independent (i.e. as long-term static creep progresses, void ratio reduction will occur and the potential for seismic settlement will reduce over time as a result). The estimated differential settlement after completion of active maintenance is sufficiently low that slope reversal and ponding is not expected to occur on a cover slope of 0.5 to 1.0 percent. In addition, the results indicate that cracking of the highly-compacted radon barrier due to settlement-induced strains is not expected.

Liquefaction analyses were performed to evaluate the risk of earthquake-induced liquefaction of the tailings. Two methods (Idriss and Boulanger, 2008; Youd et al., 2001) were used for the analyses. Material properties were obtained from results of laboratory tests on tailings samples collected during the October 2013 tailings investigation of Cells 2 and 3 (MWH, 2015b). Other parameters used were based on CPT data measured during the October 2013 tailings investigation. Results of the site-specific PSHA (MWH, 2015a) were used in the analyses and include a PGA of 0.15g for an approximate 10,000-year return period, with the mean seismic source being a magnitude (Mw) 5.5 event occurring 20 km from the site. Computed factors of safety against liquefaction range from 2.0 to 2.8. Based on the calculated factors of safety, the tailings are not susceptible to earthquake-induced liquefaction.

3.3.9 Vegetation and Biointrusion

The plant species proposed for the cover system consist of native perennial grasses, forbs, and shrubs. The use of these species in reclamation of the tailing management cells provide a permanent or sustainable plant cover because of the highly adapted nature of these species to existing site conditions, their tolerance to environmental stresses such as drought, fire, and herbivory, and their ability to effectively reproduce over time. These species can coexist and fully utilize plant resources to minimize the establishment of invasive weeds and deep rooted woody species on the site. Once established, the proposed seed mixture produce a grass-forb-shrub community of highly adapted and productive species that can effectively compete with undesirable species. A complete discussion of cover vegetation is provided in Appendix A.

The proposed cover system is designed to minimize both plant root and burrowing animal intrusion through the use of thick layers of soil cover (total thickness 9.5 to 10.5 ft) in combination with a highly compacted layer placed at a depth that is below the expected rooting and burrowing depths of species that may inhabit the site. Root growth and animal burrowing into the highly compacted radon attenuation layer (beginning at a depth of 4 ft) will be restricted because of the high density of this material (compaction to 95 percent relative compaction based on the standard Proctor test). In addition, both root density and the size of roots decrease at a rapid rate with rooting depth, further limiting the potential for root growth into the compacted radon attenuation layer of the cover system. A complete discussion of the biointrusion evaluation through the ET cover is presented in Appendix A.

3.3.10 Cover Material/Cover Material Volumes

Material volumes required for construction of the interim cover, final cover, and erosion protection are provided in Table 3.3-1. The quantities of materials available for construction of the cover are also provided in Table 3.3-1. A summary of the volumes of borrow stockpiles was provided in Appendix A. Sufficient quantities are available from on-site sources for the topsoil and random fill materials. The bedding and gravel materials would be obtained from off-site commercial sources. Three commercial sources have been identified as potential sources for the bedding and gravel materials. The potential off-site sources were listed in Appendix A. Sufficient quantities of material are available from the off-site sources identified.

Table 3.3-1. Reclamation Cover Material Quantity Summary

Material	Quantity Required for Reclamation (cy)	Quantity Available (Identified Sources) (cy)
Topsoil (for Erosion Protection Layer)	195,000	284,100 (on-site stockpiles)
Gravel (1-inch minus for Erosion Protection Layer)	24,000	Sufficient quantity available (off-site commercial source)
Random Fill (total for additional Layer 1 material, Layer 2, and Layer 3)	3,500,000	3,596,621 (on-site stockpiles)
Riprap (for 5H:1V side slopes and rock aprons)	38,000	Sufficient quantity available (off-site commercial source)
Riprap Bedding/Filter Layer	16,000[1]	Sufficient quantity available (off-site commercial source)

Note: Based on 6-inch thick medium sand bedding/filter layer beneath riprap.

4 MILL DECOMMISSIONING PLAN

The preliminary plans for decommissioning of the Mill are presented in the plan included as Appendix B to this Reclamation Plan. This information has been updated since the previous Reclamation Plan, Revision 5.0 (Denison, 2011c). The Preliminary Decommissioning Plan attached as Appendix B includes a description of the following activities to be performed during the decommissioning process:

- Development and implementation of health and safety procedures
- Execution of pre-decommissioning activities
- Demolition of above-ground and under-ground facilities, and placement of these materials in the Cell 1 Disposal Area or the last active tailings cell
- Excavation of contaminated subsoils from the process area and placement in the Cell 1 Disposal Area or the last active tailings cell
- Clean-up of windblown contamination and placement in the Cell 1 Disposal Area or the last active tailings cell
- Regrading and revegetation

The Plan further describes the requirements prior to demolition and the procedures to be used for specific locations within the process area, as well as requirements for personnel training, environmental monitoring, and management of water and contaminants. The work should be conducted under the EFRI Radiation Protection Manual, as directed by the site Radiation Safety Officer.

The EFRI Radiation Protection Manual for Reclamation is included as Attachment D to this Reclamation Plan.

5 REVERSION TO EXISTING COVER DESIGN

5.1 Background

On November 11, 2015, the UDEQ Division of Waste Management and Radiation Control (DWMRC) recommended EFRI develop a plan to begin reclamation of the tailings management system cells. This plan would consist of placing the cover system presented in this Plan (the "Proposed Cover System") on Cell 2 and demonstrating acceptable cover performance via a performance monitoring program.

Per the Stipulation and Consent Agreement (SCA) in development between EFRI and DWMRC, Cell 2 reclamation is planned to occur in 2 phases. Phase 1 is comprised of Layers 1 and 2 of the Proposed Cover System, and will be placed on Cell 2 along with a Primary Test Section that contains all of the Proposed Cover System, including the vegetative cover. The Primary Test Section along with a Supplemental Test Section (located off of Cell 2, and relating only to vegetative cover and erosion control) will be tested over a period of approximately 7 years (the "Cell 2 Test Period").

Under the SCA, the Cell 2 Primary Test Section and Supplemental Test Section will have to meet required performance criteria to verify the effectiveness of the Proposed Cover System and initiate Phase 2 cover placement.

5.2 Proposed Cover Design Meets all Applicable Regulatory Criteria

If the Primary Test Section and Supplemental Test Section demonstrate that the Proposed Cover System meets all applicable regulatory criteria, then:

a) Cell 2

Phase 2, comprised of Layer 3, Layer 4 and the vegetative cover of the Proposed Cover System, will be placed on Cell 2, in accordance with the SCA and Section 6.0 below;

b) Other Tailings Management System Cells being Reclaimed during Cell 2 Test Period

In the event that any other tailings management system cells are to be reclaimed during the Cell 2 Test Period, such tailings impoundments will be reclaimed by placing Phase 1 of the Proposed Cover System on the cell, and then waiting until the Cell 2 test is completed. Thereafter, reclamation of the cells will be completed in the same manner as Cell 2, in accordance with the SCA and Section 6.0 below; and

c) Other Tailings Management System Cells Being Reclaimed after Cell 2 Test Period

Upon final reclamation in accordance with Section 6.0 below, the other tailings management system cells, which had not commenced reclamation during the Cell 2 test period, would be reclaimed with the Proposed Cover System.

5.3 Proposed Cover Design Does not Meet all Applicable Regulatory Criteria

If the Cell 2 Primary Test Section and Supplemental Test Section fail to meet the required performance criteria and follow up actions (to be identified in the SCA), then:

a) Cell 2

EFRI will complete Cell 2 Phase 2 cover placement by placing Layers 2, 3, and 4 of the Existing Cover System presented in Reclamation Plan Revision 3.2b (Denison, 2011b) (the "Existing Cover System") on top of the Phase 1 layers, as follows:

i. the Cell 2 Phase 1 cover system (which includes the Proposed Cover System Layers 1 and 2) would remain in place;

ii. the Existing Cover System Layer 2, comprised of 1 ft (30.5cm) Radon Barrier (compacted clay), would be placed on top of the Cell 2 Phase 1 cover;

iii. The Existing Cover System Layer 3 comprised of 2 ft (61 cm) Frost Barrier (random fill), would be placed on top of the Existing Cover System Layer 2; and

iv. the Existing Cover System Layer 4, comprised of 3 in (7.6 cm) Rock Armor would be placed on top of Existing Cover System Layer 3.

b) Other Tailings Management System Cells being Reclaimed during Cell 2 Test Period

In the event that any other tailings management system cells are to be reclaimed during the Cell 2 Test Period, such cells will be reclaimed by placing Phase 1 of the Proposed Cover System on the cells, and then waiting until the Cell 2 test is completed. Thereafter, reclamation of the cell will be completed in the same manner as Cell 2, in accordance with the SCA and Section 6.0 below. If Phase 1 of the Proposed Cover System is not completed during the Cell 2 Test Period for any such cells, then such cells may be reclaimed with the Existing Cover System; and

c) Other Tailings Management System Cells Being Reclaimed after Cell 2 Test Period

Upon final reclamation in accordance with Section 6.0 below, the other tailings management system cells which had not commenced reclamation during the Cell 2 Test Period, would be reclaimed with the Existing Cover System.

6 MILESTONES AND SCHEDULE COMMITMENTS FOR RECLAMATION

6.1. Background

Utah Administrative Code R313-24-4, incorporating by reference 10 CFR Part 40 Appendix A Criterion 6A ("**Criterion 6A**") paragraph (1), provides that: "For impoundments containing uranium byproduct materials, the final radon barrier must be completed as expeditiously as practicable considering technological feasibility after the pile or impoundment ceases operation in accordance with a written, Commission-approved reclamation plan. (The term as expeditiously as practicable considering technological feasibility as specifically defined in the Introduction of this appendix includes factors beyond the control of the licensee.) Deadlines for completion of the final radon barrier and, if applicable, the following interim milestones must be established as a condition of the individual license: windblown tailings retrieval and placement on the pile and interim stabilization (including dewatering or the removal of freestanding liquids and re-contouring). The placement of erosion protection barriers or other features necessary for long-term control of the tailings must also be completed in a timely manner in accordance with a written, Commission-approved reclamation plan."

As contemplated by Criterion 6A, this Section sets out the interim milestones and deadlines for completion of the final radon barrier for individual tailings impoundments (referred to in this Section as "tailings impoundments" or "conventional impoundments") at the Mill after each such impoundment begins final closure. It also sets out milestones for the removal and disposal of non-conventional impoundments (referred to in this Section as "evaporation ponds" or "non-conventional impoundments") after each such impoundment begins final closure, as well as additional milestones applicable to final Mill site closure. A table that summarizes all of these milestones is included in Section 6.2.6 below.

Also included below are schedule commitments for other events or actions which are not "milestones" required under Criterion 6A, but instead are schedule commitments to be achieved in order to ensure that those events or actions are completed in a timely manner. As these schedule commitments are not milestones they do not come under the specific provisions of paragraph (2) of Criterion 6A. However, a general timeliness standard for completing those items is retained. The licensee must complete those actions in a timely way, and the Director has the authority to take action if necessary in this regard. As these schedule commitments are not milestones required under Criterion 6A(1), they are not included in the table set out in Section 6.2.5 below.

6.2. Milestones and Schedule Commitments

6.2.1. General

(a) Definition of "Operation"

"Operation" means that an impoundment is being used for the continued placement of uranium byproduct material or tailings or is in standby status for such placement. An impoundment is in operation from the day that uranium byproduct material or tailings are first placed in the impoundment until the day that final closure begins.

(b) When Final Closure of an Impoundment Begins

Final closure of an impoundment begins when the owner or operator provides written notice to the EPA and to the Director that:

i) In the case of a conventional impoundment (i.e., a tailings impoundment), the impoundment is no longer receiving uranium byproduct material or tailings, is no longer on standby status for such receipt and is being managed under an approved reclamation plan for that impoundment or facility closure plan; and

ii) In the case of a non-conventional impoundment (e.g., an evaporation pond), the impoundment is no longer required for evaporation or holding purposes, is no longer on standby for such purposes and is being managed under an approved reclamation plan for that impoundment or facility closure plan.

An approved reclamation plan prepared and approved in accordance with 10 CFR part 40, Appendix A is considered a reclamation plan for purposes of this paragraph 6.2.1(b).

(c) The Existing Tailings Management System at the Mill

The tailings management system at the Mill currently consists of three tailings impoundments: Cell 2, which is not in operation and is in final closure, and Cells 3 and 4A, which are in operation. Cell 1 is an evaporation pond. Cell 4B is currently being used as an evaporation pond and will continue to be used as an evaporation pond until it first starts to receive tailings sands or other byproduct material (other than solutions) for disposal. Future cells may commence as evaporation ponds, and will continue as evaporation ponds until they first receive tailings sands or other byproduct material (other than solutions) for disposal, at which time they will become tailings impoundments.

(d) The Proposed Cover Design and Existing Cover Design

This Plan presents a proposed evapotranspiration (ET) cover (the "**Proposed Cover Design**") as a component of the reclamation plan for the tailings impoundments, to replace the rock armor cover design (the "**Existing Cover Design**") set out in Appendix D to the Reclamation Plan Version 3.2b (Denison, 2011b).

The Stipulation and Consent Agreement described in Section 6.2.1(e) below and Section 5.0 above describe a set of circumstances under which the Final Cover Design could be the Existing Cover Design rather than the Proposed Cover Design. Section 5.0 of this Plan describes the manner in which EFRI would revert from the Proposed Cover Design to the Existing Cover Design if so required by the Stipulation and Consent Agreement.

i) The Proposed Cover Design

The Proposed Cover Design will have a minimum thickness of 9.5 feet, and will consist of the following layers listed below from top to bottom:

- Layer 4 - 0.5 ft (15 cm) thick Erosion Protection Layer (topsoil-gravel admixture or topsoil)
- Layer 3 - 3.5 ft (107 cm) thick Water Storage/Biointrusion/Frost Protection/Secondary Radon Attenuation Layer (loam to sandy clay)
- Layer 2 – 3.0 - 4.0 ft (91 to 122 cm) thick Primary Radon Attenuation Layer (highly compacted loam to sandy clay)
- Layer 1 - 2.5 ft (76 cm) thick (minimum) Secondary Radon Attenuation and Grading Layer (loam to sandy clay)

All the layers combined comprise the monolithic ET cover system.

ii) The Existing Cover Design

The Existing Cover Design will have a minimum thickness of 6 feet, and will consist of the following layers listed below from top to bottom:

- Layer 4 -- 3 in (7.6 cm) Rock Armor
- Layer 3 -- 2 ft (61 cm) Frost Barrier Layer (random fill)
- Layer 2 -- 1 ft (30.5) Radon Barrier (compacted clay)
- Layer 1 -- Minimum 3 ft (91.4 cm) Platform Fill (random fill)

(e) The Stipulation and Consent Agreement

EFRI and the Director of the UDEQ DWMRC have entered into a Stipulation and Consent Agreement (the "**SCA**"), which sets out the terms on which the Mill will test the effectiveness of the Proposed Cover Design and, together with Section 5.0 of this Plan, the circumstances in which the approved Cover Design for reclamation of tailings impoundments could be a variation of the Proposed Cover Design or the Existing Cover Design, rather than the Proposed Cover Design.

6.2.2. Deadlines, Interim Milestones and Schedule Commitments for Closure of Cell 2

The deadlines and interim milestones and schedule commitment dates for closure of Cell 2 are set out in the SCA. The requirements set out in the SCA are incorporated by reference into this Plan as if set out in this Plan. The final radon barrier for Cell 2 (Layers 1 and 2 under the Proposed Cover Design) has been put in place. Radon flux measurements taken since the final radon barrier has been placed onto Cell 2 have been well below the 20 pCi/m^2s standard set out in Criterion 6A.

6.2.3. Milestones and Schedule Commitments for Closure of a Conventional Impoundment (i.e., a Tailings Impoundment), other than Cell 2

A conventional impoundment (i.e., tailings impoundment), other than Cell 2, may begin final closure at any time, including while the Mill facility as a whole remains in operation as well as during or after final Mill site decommissioning and closure. Once final closure of a conventional impoundment begins as specified in Section 6.2.1 b) above, the final radon barrier for the impoundment shall be completed as expeditiously as practicable thereafter considering technological feasibility (including taking into consideration factors beyond the control of the licensee) in accordance with this Plan and the deadlines, milestones and schedule commitments set out below:

(a) Interim Stabilization (Including Dewatering or the Removal of Freestanding Liquids and Re-contouring) of the Tailings Impoundment.

i) Removal of Freestanding Liquids

Commencing on the date the impoundment begins final closure in accordance with Section 6.2.1 b) above, the addition of liquids to the tailings impoundment, other than by natural precipitation, will cease, and free standing liquids will be allowed to dry out by natural evaporation. To the extent reasonably practicable, and if excess evaporative capacity is available in other cells in the tailings management system, the Mill will transfer solutions out of the tailings impoundment and into other tailings impoundments and/or evaporation ponds in order to enhance evaporation and removal of solutions from the impoundment. This item must be completed within one year after the impoundment begins final closure. This deadline is a milestone as required by Criterion 6A(1), and is subject to the provisions of Criterion 6A(2).

ii) Re-contouring

Re-contouring of the tailings impoundment, in accordance with Drawings and Attachment A (Technical Specifications) of this Plan ("**Re-contouring**"), will commence upon removal of freestanding liquids from the impoundment and must be completed within two years after the impoundment begins final closure. This deadline is a milestone as required by Criterion 6A(1), and is subject to the provisions of Criterion 6A(2).

iii) Commencement of Dewatering

Dewatering of the impoundment shall commence upon completion of re-contouring of the impoundment, and shall continue until the impoundment is dewatered as contemplated by item 6.2.3(a)(vii) below. This deadline is a milestone as required by Criterion 6A(1), and is subject to the provisions of Criterion 6A(2).

iv) Placement of Layer 1

Upon completion of re-contouring of the impoundment, EFRI will complete placement of Layer 1 (Secondary Radon Attenuation and Grading Layer under the Proposed Cover Design or Platform Fill under the Existing Cover Design, as applicable) on the impoundment, in accordance with this Plan. This item must be completed within three years after the date the impoundment begins final closure. This deadline is a milestone as required by Criterion 6A(1), and is subject to the provisions of Criterion 6A(2).

v) Placement of Layer 2 (Final Radon Barrier)

Upon EFRI being satisfied that there have been decreasing trends in settlement followed by a maximum of 0.1 feet (30 mm) of cumulative settlement over 12 months (for at least 90 percent of the settlement monuments), or at such earlier time as EFRI may determine, EFRI shall commence placing Layer 2 (the Primary Radon Attenuation Layer under the Proposed Cover Design or the Radon Barrier under the Existing Cover Design, as applicable) on the impoundment. This item must be completed as expeditiously as practicable considering technological feasibility (including factors beyond the control of the licensee), but in any event within seven years after the impoundment begins final closure. This deadline is a milestone as required by Criterion 6A(1), and is subject to the provisions of Criterion 6A(2).

vi) Placement of Layer 3

After placement of Layer 2, EFRI will place Layer 3 (the Water Storage/Biointrusion/Frost Protection/Secondary Radon Attenuation Layer under the Proposed Cover Design or the Frost Barrier Layer under the Existing Cover Design, as applicable) on the impoundment. Timing of commencement of this item will be at the discretion of EFRI, and Layer 3 may be placed prior to or after completion of dewatering. The schedule commitment for this item is to have it completed within the later of (A) seven years after the impoundment begins final closure and (B) two years after completion of placement of Layer 2 on the impoundment, or such later date as may be approved by the Director. This item is not a milestone required under Criterion 6A(1) because it follows placement of the final radon barrier and is not required for that action, and because there is a separate milestone for dewatering. Instead, this item is included as a schedule commitment to be achieved in order to ensure that the activity is completed in a timely manner. As this schedule commitment is not a milestone it does not come under the specific provisions of paragraph (2) of Criterion 6A. However, a general timeliness standard for completing this activity is retained. EFRI must complete this activity in a timely way, and the Director has the authority to take action if necessary in this regard.

vii) Completion of Dewatering

Dewatering shall be considered to be complete when, after the placement of Layer 2 and Layer 3 (if Layer 3 is placed prior to completion of dewatering) decreasing trends in settlement followed by a maximum of 0.1 feet (30 mm) of cumulative settlement over 12 months (for at least 90 percent of the settlement monuments) have occurred. This item must be completed within the later of (A) seven years after the impoundment begins final closure and (B) two years after completion of placement of Layer 2 on the impoundment. This deadline is a milestone as required by Criterion 6A(1), and is subject to the provisions of Criterion 6A(2).

viii) Placement of Layer 4 Under the Proposed Cover Design

Placement of Layer 4 under the Proposed Cover Design (Erosion Protection Layer) on the impoundment will commence after the completion of dewatering (this item does not apply to the Existing Cover Design). The schedule commitment for this item is to have it completed within the later of (A) eight years after the impoundment begins final closure and (B) two years after completion of placement of Layer 3 on the impoundment, or such later time as may be approved by the Director. This item is not a milestone required under Criterion 6A(1), because it follows placement of the final radon barrier and is not required for that activity. Instead, this item is included as a schedule commitment to be achieved in order to ensure that the activity is completed in a timely manner. As this schedule commitment is not a milestone it does not come under the specific provisions of paragraph (2) of Criterion 6A. However, a general timeliness standard for completing this activity is retained. EFRI must complete this activity in a timely way, and the Director has the authority to take action if necessary in this regard.

ix) Vegetative Cover

If the Cover Design, as approved by the Director in accordance with the procedures described in the SCA and Section 5.0 of this Plan, is the Proposed Cover Design or otherwise calls for vegetative cover on the impoundment, then revegetation of the cover will take place at the completion of placement of Layer 4 (Erosion Protection Layer) on the impoundment, in accordance with the revegetation plan set out in Appendix J to the Updated Cover Design Report. All required seeding for re-vegetation will commence in the first available growing season after the completion of placement of Layer 4 (Erosion Protection Layer) on the impoundment, as determined by the Director, and will be completed by the end of such growing season, or such later time as may be approved by the Director. This item is not a milestone required under Criterion 6A(1), because it follows placement of the final radon barrier and is not required for that activity. Instead, this item is included as a schedule commitment to be achieved in order to ensure that the activity is completed in a timely manner. As this schedule commitment is not a milestone it does not come under the specific provisions of paragraph (2) of Criterion 6A. However, a general timeliness standard for completing this activity is retained. EFRI must complete this activity in a timely way, and the Director has the authority to take action if necessary in this regard.

x) Rock Armor

If the Cover Design, as approved by the Director in accordance with the procedures described in the SCA and Section 5.0 of this Plan, is the Existing Cover Design or includes Layer 4 (Rock Armor) of the Existing Cover Design, then rock armor shall be placed on the tailings impoundment, in accordance with Reclamation Plan 3.2b (Denison, 2011b). In addition, rock armor is required for the exterior slopes of the impoundment under the Proposed Cover Design. Such placement, will commence within one year after completion of dewatering on the impoundment in accordance with Section 5.0 of this Plan, and will be completed within 180 days thereafter, or such later date as may be approved by the Director. This item is not a milestone required under Criterion 6A(1), because it follows placement of the final radon barrier and is not required for that activity. Instead, this item is included as a schedule commitment to be achieved in order to ensure that the activity is completed in a timely manner. As this schedule commitment is not a milestone it does not come under the specific provisions of paragraph (2) of Criterion 6A. However, a general timeliness standard for completing this activity is retained. EFRI must complete this activity in a timely way, and the Director has the authority to take action if necessary in this regard.

(b) Leaving a Portion of an Impoundment Open for Disposal of On-site Generated Trash or 11e.(2) Byproduct Material from ISR Operations

The License authorizes a portion of a specified impoundment to accept uranium byproduct material or such materials that are similar in physical, chemical, and radiological characteristics to the uranium mill tailings and associated wastes already in the pile or impoundment, from other sources, during the closure process, and on-site generated trash, provided that this does not result in a delay or impediment to emplacement of the final radon barrier over the remainder of the impoundment in a manner that will achieve levels of radon-222 releases not exceeding 20 pCi/m^2s averaged over the entire impoundment. Reclamation of the disposal area, as appropriate, must be completed in a timely manner after disposal operations cease in accordance with paragraph (1) of Criterion 6A; however, these actions are not required to be completed as part of meeting the deadline for final radon barrier construction for the impoundment.

(c) Windblown Tailings Retrieval and Placement on the Impoundment

As the Mill facility as a whole may still be in operation at the time the impoundment is being reclaimed, there may not be a need to retrieve any windblown tailings for placement on the impoundment at the time of final closure of the impoundment. Those activities will be required during final decommissioning of the entire Mill facility. Accordingly, the milestones associated with those activities are set out in Section 6.2.5 below.

6.2.4. Milestones and Schedule Commitments for Closure of a Non-Conventional Impoundment (e.g., an Evaporation Pond)

A non- conventional impoundment (e.g., an evaporation pond), may begin final closure at any time, including while the Mill facility as a whole remains in operation as well as during or after final Mill site decommissioning and closure. Once final closure of a non-conventional impoundment begins as specified in Section 6.2.1 b) above, final closure of the impoundment shall be accomplished in accordance with this Plan and the deadlines, milestones and schedule commitments set out below:

(a) Removal of Free-Standing Liquids from Evaporation Ponds

Commencing on the date the impoundment begins final closure in accordance with Section 6.2.1 b) above, the addition of liquids to the impoundment, other than by natural precipitation, will cease, and free standing liquids will be allowed to dry out by natural evaporation. To the extent reasonably practicable, and if excess evaporative capacity is available in other conventional or non-conventional impoundments in the tailings management system, the Mill will transfer solutions out of the impoundment and into other impoundments in order to enhance evaporation and removal of solutions from the impoundment. This item must be completed within five years after the impoundment begins final closure. Although this deadline is not a milestone required under Criterion 6A(1), because it is not linked to the placement of a final radon barrier in a non-operational tailings impoundment, EFRI agrees that for purposes of this Plan it shall be treated as a milestone as required by Criterion 6A(1), and as a result EFRI agrees that it will be subject to the provisions of Criterion 6A(2).

(b) Removal of Liners, Sediments and any Contaminated Soils from Evaporation Ponds

Upon removal of the free-standing liquids from the impoundment, the licensee shall commence removal of all liners, sediments and any contaminated soils from and under the impoundment and dispose of such materials into one or more conventional impoundments. This item must be completed within the earlier of (A) seven years after the impoundment begins final closure, and (B) three years after the removal of all free-standing liquids from the impoundment. Although this deadline is not a milestone required under Criterion 6A(1), because it is not linked to the placement of a final radon barrier in a non-operational tailings impoundment, EFRI agrees that for purposes of this Plan it shall be treated as a milestone as required by Criterion 6A(1), and as a result EFRI agrees that it will be subject to the provisions of Criterion 6A(2).

6.2.5. Additional Milestone for Final Mill Closure

If the Mill facility as a whole has commenced final reclamation, as defined in this Plan, then the following additional milestone shall apply after that time:

(a) Mill Demolition and Windblown Tailings Retrieval and Placement in a Tailings Impoundment

Mill demolition and windblown tailings retrieval, as contemplated by Attachment A (Technical Specifications) of this Plan and disposal into one or more tailings impoundments shall commence upon commencement of final closure of the entire Mill site ("Mill Final Closure"), and shall be completed within four years after commencement of Mill Final Closure. This deadline is a milestone as required by Criterion 6A(1), and is subject to the provisions of Criterion 6A(2).

It should be noted that individual conventional and non-conventional impoundments may begin final closure before, during or after commencement or completion of Mill Final Closure, and the decision to begin final closure on any particular impoundment is not tied to Mill Final Closure. The milestones and schedule commitments in Sections 6.2.3 and 6.2.4 above apply to final closure of conventional and non-conventional impoundments once they begin final closure in accordance with Section 6.2.1(b) above, whether during Final Mill Closure or otherwise. Further, as a tailings impoundment will be considered to be in operation so long as it is receiving byproduct material, which includes Mill decommissioning materials, windblown, slimes drain dewatering solutions etc., and an evaporation pond will be considered to be in operation so long as it is required for evaporation or holding purposes, it is expected that one or more tailings impoundments and evaporation ponds will continue in operation during all or part of the Mill decommissioning process. One or more impoundments may also continue in operation for licensed activities, such as direct disposal of 11e.(2) byproduct material from In Situ Recovery uranium operations or other licensed activities, after completion of Mill Final Closure.

6.2.6. Summary Table of Milestones

The following table summarizes all of the milestones required by Criterion 6A(1), all of which are described in more detail above.

As the schedule commitments described in detail above are not milestones required under Criterion 6A(1), they are not included in the following table.

	Milestone	**Reclamation Plan 5.1B Section Number**	**Start**	**End**
1. Milestones for Closure of an Individual Conventional Impoundment (Tailings Impoundment) at any Time				
1.1.	Removal of Free Standing Liquids	6.2.3(a)(i)	Date final closure of the impoundment begins in accordance with Section 6.2.1(b)	One year after impoundment begins final closure
1.2.	Re-contouring	6.2.3(a)(ii)	Upon removal of free standing liquids	Two years after impoundment begins final closure
1.3.	Commence Dewatering	6.2.3(a)(iii)	Upon completion of Re-contouring	NA

	Milestone	Reclamation Plan 5.1B Section Number	Start	End
1.4.	Placement of Layer 1 (Secondary Radon Attenuation and Grading Layer under the Proposed Cover Design or Platform Fill under the Existing Cover Design, as applicable)	6.2.3(a)(iv)	Upon completion of re-contouring	Three years after impoundment begins final closure
1.5.	Placement of Layer 2 (Final Radon Barrier) (the Primary Radon Attenuation Layer under the Proposed Cover Design or the Radon Barrier under the Existing Cover Design, as applicable)	6.2.3(a)(v)	Upon EFRI being satisfied that there have been decreasing trends in settlement followed by a maximum of 0.1 feet (30 mm) of cumulative settlement over 12 months (for at least 90 percent of the settlement monuments), or at such earlier time as EFRI may determine	As expeditiously as practicable considering technological feasibility (including factors beyond the control of the licensee), but in any event within seven years after impoundment begins final closure
1.6.	Completion of Dewatering	6.2.3(a)(vii))	NA	Within later of (A) seven years after impoundment begins final closure and (B) two years after completion of placement of Layer 2
2. Milestones for Closure of a Non-Conventional Impoundment (Evaporation Pond) at any Time				
2.1.	Removal of Free Standing Liquids	6.2.4(a)(i)	Date final closure of the impoundment begins in accordance with Section 6.2.1(b)	Five years after impoundment begins final closure
2.2.	Removal of Liners, Sediments and any Contaminated Soils from Impoundment	6.2.4(a)(ii)	Upon removal of the free-standing liquids from the impoundment	Earlier of (A) seven years after the impoundment begins final closure, and (B) three years after the removal of all free-standing liquids from the impoundment

	Milestone	Reclamation Plan 5.1B Section Number	Start	End
3. Additional Milestone Applicable to Mill Final Closure				
	Mill Demolition and Windblown Tailings Retrieval and Placement in a Tailings Impoundment	6.2.5(a)	Upon commencement of Mill Final Closure	Four years after Commencement of Mill Final Closure

NOTE:
DRAWINGS REC-0 THROUGH REC-3 PRESENT THE OVERALL RECLAMATION PLANS FOR THE ENTIRE WHITE MESA MILL SITE. DRAWINGS TRC-1 THROUGH TRC-10 PRESENT THE RECLAMATION PLANS FOR THE CELLS USED FOR TAILINGS DISPOSAL OR PROCESS WATER EVAPORATION (CELLS 1, 2, 3, 4A, AND 4B).

CELLS 1 AND 4B ARE CURRENTLY USED FOR PROCESS WATER EVAPORATION. THE RECLAMATION PLANS REFLECTED IN THESE DRAWINGS ARE BASED ON POTENTIAL USE OF CELL 4B IN THE FUTURE FOR TAILINGS DISPOSAL.

TECHNICAL SPECIFICATIONS FOR

RECLAMATION OF WHITE MESA MILL FACILITY

BLANDING, UTAH

TABLE OF CONTENTS

1.0 SPECIAL PROVISIONS

1.1 Scope of Document

The following technical specifications have been prepared for reclamation and decommissioning of the Energy Fuels Resources (USA) Inc. (”EFRI”), White Mesa Uranium Mill Facility (“Mill”) in Blanding, Utah. These technical specifications have been prepared for review and approval by the Utah Department of Environment Quality (“DEQ”), Division of Waste Management and Radiation Control (“DWMRC”) and are submitted as an attachment to the Reclamation Plan. The design drawings for reclamation are attached and are designated as the “Drawings”. The Construction Quality Assurance/Quality Control Plan (“CQA/QC Plan”) referenced in this document is provided as Attachment B to the Reclamation Plan. The Technical Specifications have been written assuming tailings management Cells 2, 3, 4A, and 4B will receive tailings to the maximum permitted tailings elevations. Cell 2 is full and partially reclaimed. Cell 3 was used for tailings storage, but is currently only receiving mill waste. Cell 3 is partially full and partially reclaimed. Cell 4A is the only cell currently receiving tailings and is partially full. Cell 4B is used for evaporation of process solutions and has not been used for storage of tailings. The Technical Specifications have been written assuming Cell 4B will be used in the future for tailings storage.

These technical specifications have been written assuming (a) a contractor will conduct tailings impoundment reclamation under contract with EFRI and under EFRI’s direction (b) the work quality will be checked with independent (third-party) construction quality assurance, and (c) the tailings management system comprised of Cells 2, 3, 4A, and 4B will receive tailings to the maximum permitted tailings elevations.

1.2 Definitions and Roles

Construction Quality Assurance (CQA) – A planned and systematic pattern of means and actions designed to assure adequate confidence that the materials or services meet contractual and regulatory requirements and will perform satisfactorily in service. CQA refers to means and actions employed by the involved parties to assure conformity of the project work with the CQA/QC Plan, the Drawings, and the Technical Specifications.

Construction Quality Control (CQC) – Actions which provide a means to measure and regulate the characteristics of an item or service in relation to contractual and regulatory requirements. CQC refers to those actions taken by the Contractor, technicians, or other involved parties to verify that the materials and the workmanship meet the requirements of the CQA/QC Plan, the Drawings, and the Technical Specifications.

Technical Specifications – The document that prescribes the requirements and standards for the specific elements of the reclamation. The Technical Specifications will be prepared in final form prior to commencement of reclamation activities.

Drawings – The detailed project drawings to be used in conjunction with the Technical Specifications. The Drawings will be prepared in final form as construction drawings prior to reclamation.

Construction Project – The total authorized/approved reclamation project that requires several construction segments to complete.

Construction Segment – A portion of the total construction project involving a specific area or type of work. Several construction segments will likely take place simultaneously during reclamation.

Construction Task – A basic construction feature of a construction segment involving a specific construction activity.

ASTM Standards – The latest versions of the American Society for Testing and Materials specifications, procedures and methods.

For the Technical Specifications, EFRI is referred to as the **Owner**, with overall responsibility for closure, as well as site reclamation.

The on-site **Construction Manager** is responsible for the conduct, direction and supervision of all reclamation activities as detailed in the Drawings and Technical Specifications.

The **Design Engineer** is responsible for the design of the various elements of the reclamation project and for preparing the Drawings and Technical Specifications.

The **Contractor** is defined as the group (or groups) selected by the Owner and responsible for conducting the work tasks outlined in Section 1.3 under the direction of, and under contract with the Owner.

The **Surveyor** is a party, independent from the Owner or Contractor, who is responsible for surveying, documenting, and verifying the location of all significant components of the work.

The **CQA/QC Consultant** is a party, independent from the Owner or Contractor, who is responsible for observing, testing, and documenting the various activities comprising the Reclamation Project in accordance with the CQA/QC Plan, the Technical Specifications and the Drawings.

The **CQA Officer** will be responsible for overall implementation and management of the CQA/QC Plan for the reclamation project.

The **CQA Site Manager** will be appointed by the CQA Consultant to provide day-to-day, on-site oversight of the CQA/CQC activities. The CQA Site Manager could be an employee of the Owner or a third-party consultant.

The CQA Consultant will utilize various **QC Technicians** to assist the on-site CQA Site Manager to perform specific tasks throughout the project to verify the adequacy of construction materials and procedures.

The **Document Control Officer** will be appointed by the Construction Manager to assist with managing the various documents that will be produced throughout the project.

The **CQA Laboratory** is a party, independent from the Owner and Contractor, responsible for conducting tests of soils and other project materials in accordance with ASTM and other applicable standards in either an on-site or off-site laboratory.

The **DWMRC Project Manager** will represent the DWMRC's interests in the reclamation project.

The CQA/QC Plan (Attachment B of the Reclamation Plan) contains more detailed descriptions of the project roles.

1.3 Scope of Work

The work outlined in these Technical Specifications consists of execution of the following tasks associated with reclamation of the tailings management system and associated site reclamation.

- Preparation of borrow areas for material excavation by removal of vegetation; and stripping, salvaging, and stockpiling of topsoil;
- Preparation of material staging and stockpile areas by removal of vegetation; stripping, salvaging, and stockpiling of topsoil; and providing for storm water diversion and internal water collection;
- Removal of raffinates and PVC liner materials from Cell 1 and placement within the last active tailings cell;
- Construction of a clay-lined disposal cell (Cell 1 Disposal Area) along the Cell 1 containment dike for disposal of mill demolition debris and contaminated soils;
- Construction of a sedimentation basin in the location of Cell 1 (does not include the Cell 1 Disposal Area);
- Excavation of process area structure foundations, paved areas, concrete pads and roadways, and placement of these materials in the disposal cell;
- Excavation of contaminated subsoils from the process area, and placement in the last active tailings cell or the Cell 1 Disposal Area.
- Construction of the cover system over the tailings cells, with placement of topsoil and/or topsoil-gravel admixture over the disposal cell cover surface.
- Regrading and placement of topsoil over excavated areas, stockpile and staging areas, and other disturbed areas of the site.
- Establishment of vegetation on the disposal cell surface and surrounding reclaimed areas on site.

The Technical Specifications have been written assuming tailings management Cells 2, 3, 4A, and 4B will receive tailings to the maximum permitted tailings elevations. Cell 2 is full and partially reclaimed. Cell 3 was used for tailings storage, but is currently only receiving mill waste. Cell 3 is partially full and partially reclaimed. Cell 4A is the only cell currently receiving tailings and is partially full. Cell 4B is used for evaporation of process solutions and has not been used for storage of tailings. The Technical Specifications have been written assuming Cell 4B will be used in the future for tailings storage.

Work not included in these Technical Specifications consists of salvage of facility equipment, demolition of facility structures, groundwater monitoring and remediation, and post-reclamation performance monitoring.

1.4 Applicable Regulations and Standards

The work will be conducted to conform with applicable Federal, State, and County environmental and safety regulations, as well as applicable conditions in the Owner's radioactive materials license. Geotechnical testing procedures will follow applicable ASTM standards, as documented in the most current edition of standards in force at the start of work. Personnel safety procedures and monitoring will be conducted in accordance with the Owner's Radiation Protection Manual for Reclamation Activities and as directed by the Radiation Safety Officer ("RSO").

1.5 Permits

The work will be conducted under the Owner's existing radioactive materials license and State of Utah Air Quality Approval Order (DAQE-AN0112050018-11, issue date March 3, 2011). The Contractor will be responsible for applying for, and obtaining (permit fees included), all other necessary permits required to complete the work outlined in these Technical Specifications.

1.6 Inspection and Quality Assurance

In general, the QA/QC Plan details the Owner's organizational structure and responsibilities, qualifications of personnel, operating procedures and instructions, record keeping and document control, and quality control in the sampling procedure and outside laboratory. The Plan will adopt the existing quality assurance/quality control procedures utilized in compliance with the existing license.

The RSO (and approved assistants as needed) will conduct on-site training, and full-time personnel monitoring, and inspection of construction activities while the site reclamation work is in progress. The RSO (and assistants) will be independent representatives of and appointed by the Owner. The responsibilities and duties of the RSO shall be as outlined in the Owner's Protection Manual for Reclamation.

The CQA Site Manager (and approved assistants as needed) will provide on-site inspection of all construction activities and quality assurance testing outlined in these Technical Specifications and the CQA/QC Plan while the construction work is in progress. The CQA Site Manager and assistants will be independent representatives of and appointed by the Owner. The inspection and CQA testing conducted by the CQA Site Manager will be under the supervision of the Reclamation Project Manager. Inspection and CQA testing will include the tasks described in the CQA/QC Plan and listed below.

a. Observation of construction practices and procedures for conformance with the Technical Specifications.
b. Testing material characteristics to ensure that earthen materials used in the construction conform to the requirements in the Technical Specifications.
c. Documentation of construction activities, test locations, samples, and test results.
d. Notification of results from quality assurance testing to the Owner and the Contractor.
e. Documentation of field design modifications or approved construction work that deviates from the Technical Specifications.

The CQA Site Manager will record the documentation outlined above on a daily basis. The Reclamation Project Manager will approve deviations from the Technical Specifications (if necessary), with notification to the Owner and DWMRC or other appropriate Utah state regulatory agency personnel. Quality control procedures have been developed for reclamation and presented in Attachment B of this Reclamation Plan. Procedures will be used for testing, sampling, and inspection functions.

1.7 Construction Documentation

During construction, the CQA Site Manager will record documentation of construction inspection work on a daily basis. Documentation will include the following items.

a. Work performed by the Contractor.
b. CQA testing and surveying work conducted.
c. Discussions with the Owner and the Contractor.
d. Key decisions, important communications, or design modifications.
e. General comments including: weather conditions, work area surface conditions, and visitors to the site.

All earthwork test results will be documented on a daily basis, with a copy of the results given to the CQA Site Manager by the end of the following working day after the testing.

The CQA Site Manager or his representative will take photographs of key construction activities and critical items for documentation.

A final construction completion report, documenting the as-built conditions of the tailings impoundment reclamation components will be submitted to DWMRC at the end of construction. This report will include the following items.

a. All design modifications or changes to the Technical Specifications that were made during construction.

b. An as-built layout of the facility prior to, and at the completion of reclamation construction.

c. An as-built layout of other reclaimed areas of the site.

d. Documentation of soil cleanup verification work (soil radiation survey and soil sampling and analyses) in areas of contaminated soil excavation.

e. Documentation of the revegetation work (soil amendments, seed mix, and vegetation establishment).

1.8 Design Modifications

Design modifications (due to unanticipated site conditions or field improvements to the design) will be made following the protocol outlined below.

a. Communication of modification with the Reclamation Project Manager.
b. Submittal to, and review by, DWMRC for approval prior to implementation.
c. Documentation of modification(s) in the construction completion report.

1.9 Environmental Requirements

The Contractor shall store materials, confine equipment, and maintain construction operations according to applicable laws, ordinances, or permits for the project site. Fuel, lubricating oils, and chemicals shall be stored and dispensed in such a manner as to prevent or contain spills and prevent said liquids from reaching local streams or groundwater. If quantities of fuel, lubricating oils or chemicals exceed the threshold quantities specified in Utah regulations, the Contractor shall prepare and follow a Spill Prevention Control and Countermeasures Plan (SPCCP), as prescribed in applicable Utah regulations. The Owner will approve said plan. Used lubricating oils shall be disposed of or recycled at an appropriate facility. The Contractor shall be responsible for disposal of all waste associated with the project work.

1.10 Water Management

The Contractor shall construct and maintain all temporary diversion and protective works required to divert storm water from around work areas. The Contractor shall furnish, install, maintain, and operate all equipment required to keep excavations and other work areas free from water in order to construct the facilities as specified.

Water required by the Contractor for dust suppression or soil-moisture conditioning will be obtained from the Owner.

1.11 Historical and Archeological Considerations

The Contractor shall immediately notify the Owner if materials of potential historical or archeological significance are discovered or uncovered. The Owner may stop work in a specific area until the materials can be evaluated for historical, cultural, or archeological significance. All materials determined to be of significance will be protected during the work, as determined by appropriate regulatory agencies, including removal or adjustment of work areas.

1.12 Health and Safety Requirements

Work outlined in these Technical Specifications will be conducted under the Owner's Radiation Protection Manual for Reclamation Activities, as directed by the RSO.

The Contractor shall suspend construction or demolition operations or implement necessary precautions whenever (in the opinion of the Reclamation Project Manager or RSO) unsatisfactory conditions exist due to rain, snow, wind, cold temperatures, excessive water, or unacceptable traction or bearing capacity conditions. The CQA Site Manager, Reclamation Project Manager, and RSO each have the authority to stop Contractor work if unsafe conditions or deviations from Technical Specifications are observed.

1.13 Personnel Monitoring

Programs currently in place for monitoring of exposures to employees will remain in effect throughout the time period during which tailings cell reclamation, mill decommissioning and clean up of windblown contamination are conducted. These programs will include personnel monitoring and the ongoing bioassay program. Access control will be maintained at the Restricted Area boundary to ensure employees and equipment are released from the site in accordance with the current License conditions. In general, no changes to the existing programs are expected and reclamation activities are not expected to increase exposure potential beyond the current levels. The Owner will assign an employee to act as RSO responsible for assuring site workers comply with the Owner's Radiation Protection Manual for Reclamation Activities and the requirements set forth in the Owner's radioactive materials license.

1.14 Environmental Monitoring

Existing environmental monitoring programs will continue during the time period in which reclamation and decommissioning is conducted as applicable. This includes monitoring of surface and groundwater, airborne particulates, radon, soils and vegetation, according to the existing License conditions as applicable. As site features are reclaimed, monitoring programs for those features may cease. Any changes will be approved by DWMRC prior to the cessation of monitoring. In general, no changes to the extent of the existing programs are expected because reclamation activities are not expected to increase exposure potential beyond the current levels.

2.0 SITE CONDITIONS

2.1 Site Location

The White Mesa Mill site is located about 6 miles south of Blanding, Utah in San Juan County, along County Road 191.

2.2 Climate and Geology

The climate of southeastern Utah is classified as dry to arid continental. Although varying somewhat with elevation and terrain, the climate in the vicinity of the Mill can be considered as semi-arid with normal annual precipitation of about 13.3 inches. The mean annual relative humidity is about 44 percent and is normally highest in January and lowest in July. The average annual Class A pan evaporation rate is 68 inches (NOAA, 1977), with the largest evaporation rate typically occurring in July. (Denison, 2009)

The Mill is located within the Blanding Basin of the Colorado Plateau physiographic province. The average elevation of the site is approximately 5,600 ft (1,707 m) above mean sea level (amsl). Typical of large portions of the Colorado Plateau province, the rocks underlying the site are relatively undeformed. The site is underlain by unconsolidated alluvium and indurated sedimentary rocks consisting primarily of sandstone and shale. The alluvial materials consist mostly of aeolian silts and fine-grained aeolian sands with a thickness varying from a few feet to as much as 25 to 30 ft (7.6 to 9.1 m) across the site. The alluvium is underlain by the Dakota Sandstone and Burro Canyon Formation, which are sandstones having total thicknesses ranging from approximately 100 to 140 ft (31 to 43 m). (Denison, 2009)

2.3 Past Operations

The mill is a uranium/vanadium mill that was developed in the late 1970's by Energy Fuels Nuclear, Inc. (“EFN”) as an outlet for the many small mines located in the Colorado Plateau and for the possibility of milling Arizona strip ores. Construction on the tailings area began on August 1, 1978. The Mill was operated by EFN from the initial start-up date of May 6, 1980 until the cessation of operations in 1983 and then intermittently under different ownership through present-day. Denison (then named International Uranium (USA) Corporation), and its affiliates, purchased the assets of EFN in May 1997. Energy Fuels Resources (USA), Inc. purchased the facility in 2012 and is the current owner.

2.4 Facilities Demolition

Demolition of equipment, structures, and associated facilities at the Mill site will be conducted according to applicable conditions of the radioactive materials license, the demolition plan for the facility, and the Owner's Radiation Protection Manual for Reclamation Activities. Facilities demolition is not included in this document.

2.5 Disposed Materials

Materials to be placed in the disposal and tailings cells consists of process waste materials, structural debris, underlying liner materials, and subsoils from planned site cleanup activities. Additional detail on each material type is outlined later in the Technical Specifications. The four major types of materials are outlined below:

- Raffinate Crystals – located in Cell 1
- Synthetic Liner – PVC liner from Cell 1
- Contaminated Soils - soils located in and around the Mill site with concentrations exceeding prescribed unity rule concentrations (see Section 6)
- Mill Debris – all equipment and structures from the demolition of the mill

2.6 Construction Materials

Construction materials for the disposal cell liner, cover system, and for erosion protection of the cover and discharge channel will include soils and aggregates from on-site and off-site sources. These materials are outlined below.

2.6.1 Liner Materials

The disposal cell will be constructed, prior to the placement of contaminated soils and mill demolition debris, with a compacted clay liner. The soils will be obtained from suitable materials stockpiled on site during cell construction.

2.6.2 Random Fill

Random fill will be used within the disposal cell and tailings cells, placed on and around mill material and debris and placed for the components of the cover system. Fill materials will be obtained from soils stockpiled on site.

2.6.3 Topsoil

Topsoil for the surface of the disposal cell and surrounding areas to be revegetated will be obtained from on-site stockpile areas.

2.6.4 Topsoil-Gravel Admixture

A mixture of gravel and topsoil will be used in select areas on the cover. The sources of rock are nearby commercial sources of alluvial gravel. Topsoil-gravel admixture shall meet the particle-size distribution requirements outlined in Section 8.

2.6.5 Riprap

A layer of riprap will be placed on the side slopes and on the perimeter apron of the disposal cell as well as within the discharge channel. The sources of riprap are nearby commercial sources of alluvial gravel and cobbles. Riprap shall meet the particle-size distribution and durability requirements outlined in Section 8, and shall meet requirements for rock durability outlined in NRC (1990) and Johnson (1999, 2002).

2.6.6 Filter Materials

Filter layer materials will be obtained from an off-site local commercial source or from select on-site borrow areas.

2.6.7 Granular Materials

Granular materials will be used for filter material and may also be used for subsurface fill for the cell base. These materials will be obtained from off-site commercial sources of alluvial sand and gravel.

2.7 Staging and Stockpile Areas

Areas on site identified as staging areas or stockpile locations will be approved by the Owner. These areas will be constructed and used in a manner consistent with the Owner's plans for storm water management. The Contractor shall maintain proper erosion control measures for stockpiles and may be required to cover piles in situations where precipitation is anticipated.

2.8 Access and Security

Access to the site will be controlled at gated entrances in the existing restricted area fencing. All gated entrances and security for the Mill property will be maintained by the Owner.

2.9 Utilities

Utilities on site will be maintained by the Owner outside of work areas (areas to be demolished or reclaimed). Utilities inside of work areas will be provided and maintained by the Contractor.

2.10 Sanitation Facilities

The Contractor, in accordance with the Owner's Radiation Protection Manual for Reclamation Activities, will maintain sanitation facilities required during construction.

3.0 WORK AREA PREPARATION

3.1 General

This section describes the preparation of site areas for reclamation. This work will be conducted according to applicable sections of the Owner's Radiation Protection Manual for Reclamation Activities.

3.2 Water Management

Preparation for work in the site area will include water management tasks outlined below.

a. Removal of raffinate crystals from Cell 1.

Breaching of the Cell 1 dike for constructing the cell as a sedimentation basin. Re-routing runoff from the mill area and areas immediately north of the cell into the sedimentation basin for discharge onto the natural ground via the channel to be located at the southwest corner of the basin.

Diversion of clean area storm water runoff from work areas (where facilities demolition and material excavation will take place) and from the disposal cell footprint area.

Collection of storm water runoff from within the work areas and the disposal cell footprint for treatment and permitted discharge, or for disposed material compaction or dust control. The planned storage location for this affected storm water is the sedimentation pond.

Isolation of water used for processing operations associated with reclamation from storm water runoff. Water from processing operations or other contaminated water will not be used for disposal cell construction.

3.3 Cell Construction

A clay-lined disposal area will be constructed within Cell 1 (Cell 1 Disposal Area) for permanent disposal of contaminated material and debris from Mill site decommissioning. The disposal area will be located immediately north of the existing dike between Cells 1 and 2. The disposal footprint area will be lined with a compacted clay liner prior to placement of contaminated materials and installation of the final reclamation cover. If there is not sufficient debris, rubble and contaminated soil to fill the Cell 1 Disposal Area as designed, the footprint of the Cell 1 Disposal Area can be reduced to decrease the horizontal dimension extending out from Cell 2 and the lateral extent of the disposed materials, to be closer to the base of the Cell 2 dike. If a design modification is required for the Cell 1 Disposal Area, it will be submitted to DWMRC for review and approval, and these Technical Specifications will be revised accordingly.

3.4 Soil Borrow Areas

Fill cover and liner materials for the disposal cell will be excavated from suitable materials stockpiled in identified borrow areas on site. Specific soil borrow areas will be selected based on haul distance to the disposal cell, ease of excavation of cover material, geotechnical characteristics, uniformity of the borrow material, and acceptable radiological and geochemical characteristics.

Borrow area preparation will consist of setup for storm water management (Section 3.2) and clearing and stripping (Section 3.5).

3.5 Clearing and Stripping

In work areas with vegetation, preparation work will include tasks outlined below.

3.5.1 Clearing

Clearing of vegetation and grubbing of roots will be in identified work areas. Clearing and grubbing shall not extend beyond 20 feet from the edge of the work area, unless as shown on the Drawings or as approved by the Reclamation Project Manager.

Vegetation from clearing and grubbing may be shredded or chipped to form mulch. Alternative methods of on-site or off-site disposal or burning of stripped vegetation shall be conducted only as approved by the Reclamation Project Manager.

3.5.2 Stripping

Stripping of salvageable topsoil (if present) shall be done within the entire work area. Stripping of topsoil shall not extend beyond 10 feet from the edge of the work area, unless approved by the Reclamation Project Manager. The depth of stripping of reclamation soil shall be based on the presence of suitable topsoil and approved by the Reclamation Project Manager. Water shall be applied to the areas of excavation and soil salvage to minimize dust generation.

Topsoil shall be stockpiled in approved areas. The final stockpile surface shall be graded and smoothed to minimize erosion and facilitate interim revegetation of the stockpile surfaces.

4.0 CELL 1 DISPOSAL AREA BASE CONSTRUCTION

4.1 General

This section outlines work associated with construction of the disposal cell base (Cell 1 Disposal Area) for receipt of materials (as described in Section 7.0) within Cell 1. The Cell 1 Disposal Area will be constructed as shown on the Drawings and outlined in these Technical Specifications.

4.2 Materials Description

4.2.1 Subgrade Fill

The disposal cell footprint is likely to have an irregular surface from contaminated material excavation. Low areas of the excavated surface shall be filled with subgrade fill to form a smooth, competent foundation for clay liner construction (shown on the Drawings).

Subgrade fill will consist of off-site granular materials, or soils and weathered sedimentary rock from approved on-site excavation areas. Subgrade fill shall have a maximum size of 6 inches and shall be free from roots, branches, rubbish, and process area debris.

4.2.2 Clay Liner Material

Clay liner material shall have a maximum particle size of one inch, and shall be free from roots, branches, rubbish, and process area debris. Clay liner material shall have a minimum of 40 percent passing the No. 200 sieve and a minimum plasticity index (PI) of 15 percent.

4.3 Work Description

4.3.1 Foundation Preparation

The footprint of the disposal cell shall form a competent foundation for clay liner and cover construction. The surface of the disposal cell footprint shall be filled with subgrade fill (where required) in low areas to form a smooth, competent foundation for clay liner and cover construction. The final filled surface shall be compacted with approved construction equipment to provide a foundation surface with uniform density for clay liner placement.

4.3.2 Disposal Cell Foundation Area

The footprint of the disposal cell is established along the north side of the dike between Cells 1 and 2 (shown on the Drawings).

4.3.3 Subgrade Fill Placement

Subgrade fill (Section 4.2.1) shall be placed in lifts with a maximum loose thickness of 12 inches and compacted in excavated areas of the disposal cell footprint to meet desired grades and elevations for the disposal cell foundation.

4.3.4 Clay Liner Material Placement

Clay liner material (Section 4.2.2) shall be placed in lifts with a maximum loose thickness of 6 inches to form a continuous layer with a total minimum compacted layer thickness of 12 inches. Clay liner material shall be placed over the prepared subgrade surface of the disposal cell (Section 4.3.1).

Compaction of the clay liner material shall be done with a sheepsfoot or tamping-foot roller of sufficient weight to achieve the required compaction specifications. Compaction of the clay liner material shall not be achieved solely through the use of rubber-tired equipment.

If the moisture content of any layer of clay liner is outside of the allowable placement moisture content range specified (Section 4.4.2), the material shall be moistened and/or reworked with a harrow, scarifier, or other suitable equipment to a sufficient depth to provide relatively uniform moisture content and a satisfactory bonding surface before the next layer of clay material is placed. If the compacted surface of any layer of clay liner material is too wet (due to precipitation) for proper compaction of the fill material to be placed thereon, it shall be reworked with a harrow, scarifier or other suitable equipment to dry out the layer and reduce the moisture content to within the required limits, and re-compacted.

Clay liner construction shall minimize lenses, pockets, streaks or layers of material differing substantially in texture, gradation or moisture content from the surrounding material. Oversized material will be controlled through observation of placement by a qualified individual with authority to stop work and reject material being placed and by culling oversized material from the fill.

No clay liner material will be placed when either the materials, or the underlying material, is frozen or when ambient temperatures do not permit the placement or compaction of the materials to the specified density without developing frost lenses in the fill.

Any holes in the clay liner material resulting from testing shall be repaired by hand by filling with clay fill, or by filling with bentonite powder which is hydrated to fully seal the hole.

4.4 Performance Standards and Testing

Lifts of material with tested dry densities less than the specified values will be reworked by the Contractor as necessary and re-compacted until the specified dry density is attained. Material that is too dry or too wet to permit bonding of layers during compaction will be reworked by the Contractor until the moisture content is within the specified limits.

4.4.1 Subgrade Testing

Subgrade fill shall be placed in lifts not exceeding 8 inches in loose thickness. Each lift shall be compacted to a minimum of 90 percent of standard Proctor (ASTM D698) density and within 3 percent of the optimum moisture content for the material.

Where required, checking of compaction of compacted subgrade fill and the final subgrade surface will consist of a minimum of one field density test per 1,000 cubic yards of material compacted. A minimum of two tests will be taken for each day that more than 150 cubic yards of material is placed. A minimum of one test per lift and at least one test for every full shift of compaction operations will be taken.

Field density tests will be compared with standard Proctor tests (ASTM D698 Method A or C). Where required, standard Proctor or Maximum Index Density tests will be conducted at a frequency of at least one test per 10,000 cubic yards of material compacted, or when material characteristics show significant variation.

Field density testing will be conducted with the sand cone test (ASTM D1556) or a nuclear density gauge (ASTM D6938, or as modified by the CQA Site Manager). Correlation of nuclear density gauge results will be by comparison with results from sand cone test(s) and laboratory testing for water content(s) using the oven drying method (ASTM D2216) on similar material.

4.4.2 Clay Liner Testing

Each lift of clay liner material shall be compacted to at least 95 percent of the maximum dry density for the material, as determined by the standard Proctor test (ASTM D698). During compaction, the material shall be within 2 percent of the optimum moisture content for the material, as determined by the standard Proctor test. If water addition is required to achieve this range of moisture contents, the added water shall be thoroughly mixed into the material prior to compaction.

Material specifications for the clay liner material will be confirmed by gradation testing conducted by approved personnel. Testing will consist of No. 200 sieve wash and maximum particle size testing (ASTM D422), and Atterberg limits testing (ASTM D4318) on samples of clay liner materials, at a frequency of at least one test per 2,000 cubic yards of fill placed, or when material characteristics show a significant variation.

Compaction of the clay liner material will be checked with a minimum of one field density test per 500 cubic yards of material compacted. A minimum of two tests will be taken for each day that more than 150 cubic yards of material is placed. A minimum of one test per lift and at least one test for every full shift of compaction operations will be taken.

Field density tests will be compared with standard Proctor tests (ASTM D698 Method A or C) on the same material. Standard Proctor tests will be conducted at a frequency of at least one test per 5,000 cubic yards of material compacted, or when material characteristics show significant variation.

Field density testing will be conducted with the sand cone test (ASTM D1556) or a nuclear density gauge (ASTM D6938, or as modified by the CQA Site Manager). Correlation of nuclear density gauge results will be by comparison with results from sand cone test(s) and laboratory testing for water content(s) using the oven drying method (ASTM D2216) on similar material.

4.4.3 Grading Tolerances

The completed grading for the clay liner shall be within 1.0 foot (horizontally) of the lines as designed, and within 0.1 foot (vertically) of the elevations as designed. The final surfaces shall be smoothed to avoid abrupt changes in surface grade or areas of runoff concentration. The layer thicknesses shall meet the required minimum thicknesses.

5.0 DISCHARGE CHANNEL GRADING

5.1 General

This section outlines specifications for the work associated with excavating the discharge channel from Cell 1. Portions of the grading for the sedimentation basin may be in soil, while other areas may require rock excavation. Although the rock may be rippable, the Contractor should prepare for non-rippable rock in some of the excavation areas.

5.2 Work Description

5.2.1 Discharge Channel Excavation

The discharge channel shall be excavated to the slopes and grades and channel widths shown on the Drawings. Discharge channel excavation will include breaching of the dike on the west side of Cell 1. Riprap will not be required to armor the discharge channel where the channel is excavated into competent sedimentary rock, as verified in the field by the CQA Site Manager.

5.2.2 Grading Tolerances

Completed grading in soil for the sedimentation basin shall be within 1.0 foot (horizontally) of the lines as designed, and within 0.1 foot (vertically) of the elevations as designed. Final surfaces shall be smoothed to avoid abrupt changes in surface grade or areas of runoff concentration.

The completed grading in rock for the discharge channel and portions of the sedimentation basin shall be within 2.0 foot (horizontally) of the lines as designed, and within 0.5 foot (vertically) of the elevations as designed. The final excavated rock surfaces of the discharge channel will be below design grades and shall not be filled to make grade.

6.0 MILL DECOMMISSIONING

The following subsections describe decommissioning plans for the mill buildings and equipment, the mill site, and associated windblown contamination.

6.1 Mill Buildings and Equipment

The uranium and vanadium processing areas of the Mill, including all equipment, structures and support facilities, will be decommissioned by demolition and disposed of in tailings or buried on site as appropriate. All equipment, including tankage and piping, agitation equipment, process control instrumentation and switchgear, and contaminated structures will be cut up, removed and buried in tailings prior to final cover placement. Concrete structures and foundations will be broken up and removed. Concrete foundations may be left in place and covered with soil as appropriate.

Decommissioned areas will include the following:

- Coarse ore bin and associated equipment, conveyors and structures
- Grind circuit including semi-autogeneous grind (SAG) mill, screens, pumps and cyclones
- Three pulp storage leach tanks to the east of the mill building, including all tankage, agitation equipment, pumps and piping
- Seven leach tanks inside the main mill building, including all agitation equipment, pumps and piping
- The counter-current decantation (CCD) circuit including all thickeners and equipment, pumps and piping
- Uranium precipitation circuit, including all thickeners, pumps and piping
- Two yellow cake dryers and all mechanical and electrical support equipment, including uranium packaging equipment
- Clarifiers to the west of the mill building including the preleach thickener (PLT), clarifier, and claricone area

- The boiler and all ancillary equipment and buildings
- The entire vanadium precipitation, drying and fusion circuit
- All external tankage not included in the previous list including reagent tanks for the storage of acid, ammonia, kerosene, water, dry chemicals, etc. and the vanadium oxidation circuit
- The ammonium sulfate pad
- The uranium and vanadium solvent extraction (SX) circuit including all SX and reagent tankage, mixers and settlers, pumps and piping
- The SX building
- The mill building
- The alternate feed processing circuit
- The decontamination pads
- The office building
- The shop and warehouse building
- The sample plant building
- The reagent storage building

The sequence of demolition will proceed so as to allow the maximum use of support areas of the facility such as the office and shop areas. It is anticipated that all major structures and large equipment will be demolished using hydraulic shears. This equipment will expedite the process, provide proper sizing of the materials for transport and placement, and reduce personnel exposure to radiation and other safety hazards during the demolition. Uncontaminated or decontaminated equipment to be considered for salvage and remediation equipment will be released in accordance with the terms of License Condition 9.10 and NUREG 1575 Supplement 1, Multi-Agency Radiation Survey and Assessment of Materials and Equipment Manual (MARSAME) (NRC, 2009) as appropriate and applicable. Contaminated soils from the Mill area will be disposed of in the tailings cells in accordance with Section 7.0.

6.2 Mill Site and Windblown Contamination

Areas with contamination around the Mill site are expected to be primarily surficial, except for the claricone and ammonium sulfate pad areas, and include the ore storage area and limited surface contamination of roads. Ore and alternate feed materials will have been previously removed from the ore stockpile area. Contaminated materials at the Mill site will be excavated and be disposed in the Cell 1 Disposal Area in accordance with Section 7.0. The depth of excavation will vary depending on the extent of contamination and will be based on the criteria in Section 7.2.3, except for the claricone and ammonium pad areas which had removal depths and extents outlined in letters submitted by EFRI to the DWMRC on 10/26/12 and 12/23/13, respectively. All other 11e.(2) byproduct materials will be disposed in the tailings cells.

The Owner proposes to reclaim the Mill and surrounding land areas within the property boundary by excavating and placing wastes, demolition debris and contaminated soils into a fenced and controlled permanent disposal area. The permanent disposal area, the current restricted area, and the property boundary, are delineated in Drawing REC-1. The Owner proposes to survey and release all areas within the property boundary, excluding the Cell 1 Disposal Area and Cells 2, 3, 4A, and 4B, for unrestricted use.

Contaminants of concern are Ra-226, Th-230 and natural uranium (U-nat). The evaluation and remediation will be dictated by Ra-226, which is the contaminant with the most restrictive cleanup standard (based on the SENES Consultants, Inc. letter to EFRI dated August 15, 2012; this letter was provided as Attachment I to EFRI's Supporting Documentation for Response to Utah DWMRC Interrogatory 13/1 (SENES 2012)). The correlation between Ra-226 and the remaining two contaminants will be developed as outlined in subsequent sections of these Technical Specifications. Verification of the remediation will be established through a Wilcoxon Rank Sum (WRS) test between the study areas and local background areas. The procedure for verification will follow guidance from NUREG-1575 Multi-Agency Radiation Survey and Site Investigation Manual (MARSSIM) (NRC, 2000). The procedure will include:

- Scoping and characterization surveys: soil samples will be collected to develop a correlation between gamma radiation levels and the unity rule.
- Classification of land areas: to (MARSSIM) Class 1 through Class 3.
- Remediation of land areas driven by correlation-based prediction equation between gamma radiation and the unity rule for multiple radionuclides.
- Final Status Survey using the Wilcoxon Rank Sum (WRS) test with local background areas.

The procedure also follows the Data Quality Objective (DQO) process defined in the MARSSIM Guidance, as discussed in Section 6.6, and NUREG-1757 Volume 2 Consolidated Decommissioning Guidance, Characterization, Survey, and Determination of Radiological Criteria (NRC, 2006).

6.3 Scoping and Characterization Surveys

Areas contaminated through process activities or windblown contamination from the tailings areas will be remediated to meet applicable cleanup criteria for Ra-226, Th-230, and U-nat. Contaminated areas will be remediated such that the residual radionuclides remaining on the site, which are distinguishable from background, will not result in a dose that is greater than that which would result from the Ra-226 soil standard, that is, 5 pCi/g above background for the surface 15 cm soil layer and 15 pCi/g for the subsurface 15 cm soil layer, respectively as discussed in Section 6.6.3.3 and hereafter referred to as “5/15”.

An initial scoping survey for windblown contamination will be conducted based on analysis of pertinent past radiometric and land use information. Operational surveys of the areas surrounding the Mill and tailings area have indicated potential windblown contamination only to the north and east of the ore storage area, and to the southwest of Cell 3. The initial scoping survey will be conducted using calibrated gamma radiation instruments on 15 meter (15 m) transects. Additional surveys will be conducted in a halo, or buffer zone, around the projected impact area. The survey in the halo will be conducted using 25 m transects. Areas where no readings exceed 75 percent of the gamma radiation guideline value, as developed per Section 6.3.2, will be classified as unaffected, and will not require remediation. Areas where one or more readings exceed the gamma radiation guideline value will be further investigated to determine whether or not remediation is required.

Prior to initiating cleanup of windblown contamination, a statistically-based soil sampling program will be conducted in an area within or outside the property boundary that is similar to the areas to be remediated, to determine the average background Ra-226 concentration, or concentrations, to be ultimately used for the cleanup. Similarity, or representativeness, will be determined based on geology, soil type and soil chemistry.

Soil cleanup verification will be accomplished by use of calibrated gamma radiation instruments. Multiple instruments will be maintained and calibrated to ensure availability and consistency during remediation efforts (Section 6.3.4).

6.3.1 Scoping and Characterization Survey for the Subsurface

The subsurface will only be investigated in areas where the historical site assessment (HSA) demonstrates the possibility of contamination below the 15 cm depth. This does not include areas of windblown contamination, or the ore storage area (unless also affected by an event demonstrated by the HSA). The method for the subsurface investigation will include boreholes where soil sampling and downhole gamma radiation investigations may occur. This method will be developed based on the HSA.

6.3.2 Gamma Radiation to Unity Rule Correlation

The Owner plans to use radiation measurement instrumentation for soil background analyses, unity rule – gamma radiation correlations, verification data, and sensitivity analyses. Soil background analyses will be completed using MARSSIM methods (NRC, 2000) for background reference areas.

Soil samples taken during characterization for correlation will be analyzed by a certified laboratory to determine the on-site correlation between the gamma radiation readings and the concentration of Ra-226, Th-230 and U-nat, in the samples. Samples will be taken from:

- Areas known to be contaminated with only processed uranium materials (i.e. tailings sand and windblown contamination)
- Areas in which it is suspected that unprocessed uranium materials (i.e. ore pad and windblown areas downwind of the ore pad) are present

The actual number of samples used will depend on the correlation of the results between gamma radiation readings and the unity rule as discussed below. Windblown contamination to the northeast of the Mill area is primarily associated with the unprocessed ore from the ore storage pad. The slightly larger windblown contamination area to the southwest of the Mill area is primarily associated with the processed tailings. A minimum of 35 samples of windblown tailings (to the southwest), and 15 samples of windblown unprocessed ore materials (to the northeast) will be collected.

Sufficient samples will be collected for developing prediction equations to calculate the linear regression lines and the corresponding upper and lower 95 percent confidence levels for each of the instruments. The upper one-sided 95 percent confidence limit will be used for the guideline value for correlation between gamma radiation readings and Ra-226 concentration. Because the unprocessed materials are expected to have proportionally higher values of uranium in relation to the Ra-226 and Th-230 content, the correlation to the gamma radiation readings are expected to be slightly different than readings from areas known to be contaminated with only processed materials. Areas expected to have contamination from both processed and unprocessed materials will be evaluated using the more conservative correlation, or will be excavated to the Ra-226 standard which should ensure that the uranium is removed.

The samples will be judgmentally selected with Ra-226 concentration at three different intervals related to the guideline value (5 pCi/g above background):

- 25 percent of the guideline value
- Approximately the guideline value
- Approximately twice the guideline value for the area of interest

This selection will maximize the precision of the correlation relationship at 5.0 pCi/g above background. Background Ra-226 concentrations have been gathered over a 16-year period at sample station BHV-3 located upwind and 5 miles west of the Mill. The Ra-226 background concentration from this sampling location is 0.93 pCi/g. This value and the concentrations of U-nat and Th-230 assumed in equilibrium with the Ra-226 will be used as an interim value for the background concentration used only in the initial planning for this project (e.g. use of historical knowledge for preliminary setting of verification sample sizes). Background locations for the verification test will have the three contaminants measured at multiple locations.

Because Ra-226 has short-lived radioactive decay products that are strong gamma radiation emitters (namely Pb-214 and Bi-214), gamma radiation surveys can be effective for characterizing soil Ra-226 distributions across large areas, including on relatively small spatial scales. The well-established, effective, and widely-used analytical approach for spatially comprehensive characterization of Ra-226 concentrations in surface soils involves spatially intensive gamma radiation surveys combined with the use of gamma radiation and soil Ra-226 concentration correlations.

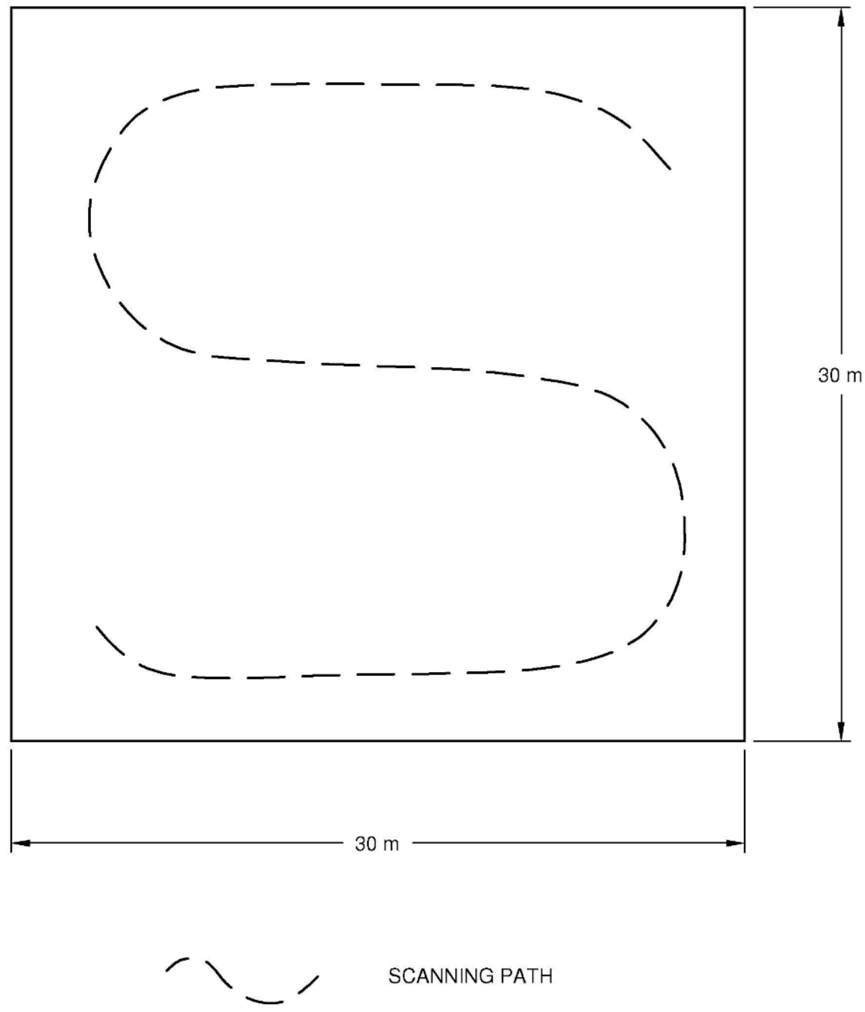
If a gamma radiation and Ra-226 concentration correlation is statistically significant, Ra-226 concentrations in surface soils can be predicted with reasonable accuracy based on gamma radiation readings collected at a high density of measurements across large areas. The same is true for other radionuclides, although correlative relationships tend to be less statistically significant and estimation uncertainty can be higher. The advantage of gamma radiation surveys is that a much higher density of measurements of terrestrial sources of gamma radiation is possible and when combined with gamma radiation/soil radionuclide correlation analysis, the approach produces a more comprehensive spatial characterization for comparisons against baseline conditions and evaluation of potential radiological contamination.

Fifteen soil samples will be collected in the restricted area to establish a correlation between the soil sampling analysis and the gamma radiation count. Additional measurement locations will be added, if necessary, to reach suitable precision, as defined in Section 6.6.3.7. The method that will be used in an effort to develop statistically significant gamma radiation/soil radionuclide correlations is as follows:

1. At each correlation plot, a 100 m^2 (10 m x 10 m) plot for correlation measurements and soil sampling will be established with pin flags. A gamma radiation scan will be performed across each correlation plot (5 m transects at a detector height of 18 inches). The average gamma radiation reading (e.g. cpm) from scan data across each correlation plot will be calculated and recorded in the field logbook, or developed using data collected from the gamma radiation scan. See Figure A-1 for the scan path.
2. Within each 10 m x 10 m correlation plot nine sub-samples of surface soils, one in the center, and eight against the edges of the plot, will be collected across the plot (at a depth of 15 cm) and composited into a single sample to represent average soil radionuclide characteristics across the correlation plot. Composite surface soil samples from each correlation plot will be submitted to a qualified commercial laboratory for analysis of U-nat, Ra-226, Th-230, Th-232 (by Ra-228), and K-40. The correlation plot scanning and sampling design for each location is illustrated in Figure A-1.
3. The laboratory chain of custody/analysis request form to be submitted with composite correlation plot soil samples will specify the following requirements:
    a. Thorough homogenization of each sample at the laboratory.
    b. Ra-226 analysis by EPA Method 901.1, modified for soil samples, with sample counting to be performed at least 21 days after sealing in the counting tin to ensure full ingrowth of Rn-222 and its decay products. Analysis of K-40 will also be conducted with EPA method 901.1, as will analysis of Ra-228 (to determine Th-232 concentrations under the assumption of radiological equilibrium).
    c. U-nat analysis by EPA Method 200.8 (ICP-MS) or equivalent, preferably with soil matrix digestion using EPA Method 3052 (microwave assisted acid digestion). EPA Method 3050B or equivalent digestive methods may alternatively be used; however, digestion will not be as complete.

d. Th-230 analysis by EPA Method 200.8 (ICP-MS) or equivalent, preferably with soil matrix digestion using EPA Method 3052 (microwave assisted acid digestion). Ten percent of the correlation plot samples will also be analyzed for Th-230 by alpha spectroscopy.

4. Upon receiving soil analysis results from the laboratory, regression analysis will be performed to determine, based on paired data from all correlation plots, if significant statistical correlations exists between average gamma radiation readings and soil Ra-226, U-nat, Th-230, Th-232 by Ra-228 and K-40 concentrations.



ENERGY FUELS	PROJECT: WHITE MESA MILL TAILINGS RECLAMATION	MWH
	TITLE: TYPICAL SCANNING PATH SCOPING SURVEY	DATE: SEP 2011 / FIGURE A-1 / FILE NAME: 1009740 SCAN PATH

6.3.3 Area Classification

The characterization and scoping surveys will be used to classify areas as either non-impacted or impacted areas. The impacted areas will be further classified into Classes 1-3 (NUREG-1575; NRC, 2000). The classification of the areas will determine the rigor required to survey and release the areas.

- Class 1 areas are areas which have, or had prior to remediation, a potential for radioactive contamination based on Mill operating history, or known contamination based on previous radiological surveys. Areas containing contamination in excess of the release criterion, specifically the Derived Concentration Guideline Level (DCGL) associated with the Wilcoxon Rank Sum Test ($DCGL_W$), established by the radium benchmark dose (RBD) approach in Section 6.6.3.3 prior to remediation should be classified as Class 1 areas. The concentration terms "$DCGL_W$", "release criterion", and "unity rule", have been used interchangeably throughout the remainder of these Technical Specifications. However, where a gamma radiation-based level is meant, the term "gamma guideline level" is used specifically.

- Class 2 areas are areas which have, or had prior to remediation, a potential for radioactive contamination or known radioactive contamination, but are not expected to exceed the $DCGL_W$.

- Class 3 areas are any impacted areas not expected to contain any residual radioactivity, or are expected to contain levels of residual radioactivity at a small fraction of the $DCGL_W$, based on Mill operating history and previous radiological surveys.

Table 6.1 - Final Status Survey Unit Classification for Land Areas

Survey Unit Classification		Statistical Test	Elevated Measurement Comparison	Sampling and/or Direct Measurements	Suggested Area (m^2)	Scanning
Impacted	Class 1	Yes	Yes	Systematic	2000	100% Coverage
	Class 2	Yes	Yes	Systematic	10,000	10-100% Systematic
	Class 3	Yes	Yes	Random	No limit	Judgmental
Non-Impacted		No	No	No	None	None

6.3.4 Remediation

Remediation will only occur in survey units that cannot pass the release criterion ($DCGL_W$). Remediation will consist of excavation of soils and placement in the tailing cells, as stated in Section 7.2.3. Remedial action support surveys will be conducted to guide the remediation. Remedial action support surveys will be conducted in a manner similar to the Final Status Surveys (FSSs), described in Sections 6.4 and 6.6, to ensure that the remedial action achieves the $DCGL_W$. Excavation will continue until the gamma radiation guideline value is achieved for surface soils.

Upon completion of remediation, gamma radiation surveys will be conducted on the excavated area and areas surrounding the excavation.

6.4 Final Status Surveys

Areas of the site will be released through the final status survey (FSS) process (see Section 6.6). Survey units will be released through FSS reports provided to DWMRC for each survey unit. Survey units that require remediation will undergo the FSS process after remediation. Survey units must meet the release criterion set forth in this section. Each survey unit that meets the release criterion will be released, pending DWMRC approval.

6.4.1 Release Criterion

Release criteria have been established and are discussed in more detail in Section 6.6.

6.4.2 Statistical Test

The WRS test will be performed using the background reference data set and the systematic sample data set from the survey unit under investigation. The background reference data set will be added to the unity rule (1) prior to the statistical test being completed. The two data sets will be derived using the weighted sum for multiple radionuclides set forth in MARSSIM (NRC, 2000):

For surface soils:

$$\frac{A\ (pCi/g\ Ra226)}{5\ (pCi/g)} + \frac{B\ (pCi/g\ \ Unat)}{545\ (pCi/g)} + \frac{C\ (pCi/g\ \ Th230)}{46\ (pCi/g)} + 1$$

For subsurface soils:

$$\frac{A\ (pCi/g\ \ Ra226)}{15\ (pCi/g)} + \frac{B\ (pCi/g\ \ Unat)}{2908\ (pCi/g)} + \frac{C\ (pCi/g\ \ Th230)}{142\ (pCi/g)} + 1$$

For instance, if the background reference area surface soil data set showed that one sample contained 2.2 pCi/g Ra-226, 2.2 pCi/g U-nat, and 2.0 pCi/g Th-230, the sample would be represented in the WRS data set as the following:

$$\frac{2.2\ (pCi/g\ \ Ra226)}{5\ (pCi/g)} + \frac{2.2\ (pCi/g\ \ Unat)}{545\ (pCi/g)} + \frac{2.0\ (pCi/g\ \ Th230)}{46\ (pCi/g)} + 1 = 1.49$$

Thus, 1.49 (unitless) for this particular background sample would be used in the WRS comparison data set for the background reference area to be compared to the survey unit data. If this sample were from the survey unit, the value would be 0.49 (unitless).

The WRS test will be performed on the survey unit and background reference area using the method in MARSSIM. For Class 1 to Class 3 survey units, the null hypothesis is that the survey unit exceeds the release criterion. If the null hypothesis is rejected, the mean for the survey unit does not exceed the $DCGL_W$, and no area exceeds the DCGL Elevated Measurement Comparison ($DCGL_{EMC}$) then the survey unit is presumed to meet the release criterion and, pending DWMRC approval, released.

If an area in a survey unit exceeds the $DCGL_W$, the area of the contamination will be determined using a mixture of soil sampling and gamma radiation surveying.

A comparison to the EMC will be made to determine if the area presents a dose equal to, or lower than, the $DCGL_W$ scenario. This determination will be completed through the derivation of area factors based on the size of hypothetical areas of contamination. The area factor for a contaminated area will be multiplied by the $DCGL_W$ to determine the allowable contaminant concentration for that size of area, which still meets the unity rule. Area factors will be determined prior to FSS's and will be approved by DWMRC.

Areas of elevated activity that do not meet the $DCGL_{EMC}$ will be remediated.

6.5 Instrument Quality Assurance/Quality Control (QA/QC)

Field gamma radiation survey instrumentation will be sodium iodide (NaI) detectors. To the extent possible, the same instruments will be use throughout the characterization, remediation and final status survey. These instruments will be cross-calibrated to allow other identical instruments or similar instruments to be used. Individuals will be appropriately trained to use the selected instrumentation and the instrumentation will be suitable for its intended use. Instrumentation shall be operated in accordance with written procedures and manufacturers' manuals which will provide guidance to field personnel on the proper use and limitations of the instruments.

6.5.1 Calibration

The manufacturer's current calibration/maintenance records will be kept on site for review and inspection for all instruments used during the survey. Past calibration records will be retained for inclusion in the FSS report.

The records will include, at a minimum, the following:

- Equipment identification (name, model, and serial number)
- Manufacturer
- Date of calibration
- Calibration due date

Instrumentation must be maintained and calibrated to manufacturer's specifications to ensure that required traceability, sensitivity, accuracy, and precision of the equipment/instruments are maintained. Instruments will be maintained and calibrated in accordance with American National Standards Institute N323A (ANSI, 1997).

6.5.2 Source and Background Checks

Prior to and after daily use, instruments will be QC-checked by comparing the instrument's response to a designated gamma radiation source and to ambient background. Prior to commencement of field operations, a site reference location will be selected for the performance of these checks. Acceptable ranges (count rate) for each instrument will be established by performing a series of counts. The acceptable range will be ± 2 sigma of the mean of the series of counts. QC source checks will consist of one-minute integrated counts with the designated source position in a reproducible geometry, performed at the designated location. Background checks will be performed in an identical fashion with the source removed. Results of the background and QC checks will be recorded in a field logbook.

Instrument response to the designated QC check source will be plotted on control charts or in tabular form (spreadsheets) and evaluated against the average source and background readings established at the start of the field activities. A performance criterion of +/– 2 sigma of this average will be used as an investigation action level, and a repeat of the measurement will be performed. A performance criterion of +/– 3 sigma of this average will be used as a failure level requiring corrective action. Results exceeding this criterion will be investigated and appropriate corrections to instrument readings will be made if the response is affected by factors beyond personnel control, such as large humidity or temperature changes. The instrument(s) in question will be removed from service while investigations and corrective actions are in progress.

Instrument response to ambient background will be used to establish a mean background response for each instrument, to monitor gross fluctuations in background activity (e.g., from changes in barometric pressure and other, non-contaminant related causes), and to evaluate detector response. The background measurements are performed for the purpose of checking for detector contamination and electronic stability (especially cabling).

Instrument response to source checks are used to prove detector efficiency and electronics stability.

During QC checks, instruments shall be inspected for physical damage, current calibration and erroneous readings. The individual performing these tasks shall document the results in accordance with the instrument protocol within MARSSIM, as provided in Exhibit A-1. Instrumentation that does not meet the specified requirements of calibration, inspection, or response check will be removed from operation. If the instrument fails the QC response check, any data obtained to that point, but after the last successful QC check will be considered invalid due to potentially faulty instrumentation.

6.6 Data Quality Objectives

This plan was developed using guidance from MARSSIM to ensure surveys are conducted with the proper rigor, quality assurance, and statistical analysis to make proper decisions. A key step in the MARSSIM process is the development of DQOs. DQOs ensure collection of data of the right type, quality, and quantity to support decisions, the decommissioning process, and the achievement of the desired end state. The DQOs are outlined below, and include systematic processes to:

1) State the problem
2) Identify the goal of the characterization
3) Identify inputs to the decision
4) Define the study boundaries
5) Develop the decision rules/analytical approach
6) Define acceptable decision errors
7) Optimize the design

6.6.1 State the Problem

Ultimately, the mill will be decommissioned, the demolition and decommissioning waste disposed in the tailings cells, and the tailings system reclaimed as approved by DWMRC. The reclamation objective is to release the mill's land areas, other than the tailings area, for unrestricted use. Land areas may have radiological contamination from milling operations. The scanning procedure needs to identify and distinguish areas that can be released, from areas that must be remediated prior to being released. The data collected following excavation in remediation areas must also be suitable for use in the FSS to demonstrate that the clean-up criteria have been met.

6.6.2 Identify the Decisions

The decision process will be based on data from scoping and characterization surveys, gamma radiation correlation, remediation and final status surveys.

Survey and sampling data will be used to:

1) Assist in classification of survey units

2) Determine areas requiring remediation

3) Develop Final Status Surveys to verify that clean-up criterion has been met

6.6.3 Identify Inputs to the Decision

6.6.3.1 Characterization and Scoping

HSAs, scoping surveys, and characterization surveys will be used to determine the extent of the contamination as well as the presence of useable relationships/ratios between the radionuclides of background reference areas. The presence of useable relationships will be established in accordance with Section 4.5 of MARSSIM (NRC, 2000). Soil sampling will be conducted in the survey areas and samples will be analyzed for U-nat, Th-230 and Ra-226.

The background must be correctly characterized and a proper background reference area chosen to represent the background for the Mill soils. This will ensure that the soil will be cleaned up to the appropriate level. Goals of the characterization include selecting an appropriate background reference area(s) and appropriate background(s), and correctly comparing selected background(s) with the survey units. Multiple backgrounds may be selected for different survey units depending on the characterization and scoping surveys in conjunction with the HSA.

From MARSSIM Section 4.5, a site background reference area should have similar physical, chemical, geological, radiological, and biological characteristics as the survey unit being evaluated. Background reference areas are normally selected from non-impacted areas, but are not limited to natural areas undisturbed by human activities. In some situations, a reference area may be associated with the survey unit being evaluated, but cannot be potentially contaminated by site activities. For example, background measurements may be taken from core samples of a building or structure surface, pavement, or asphalt. The selected reference areas will be reviewed with DWMRC.

Systematic soil sampling will occur prior to the FSS, and samples will be analyzed for Ra-226, Th-230, and U-nat to determine background concentrations to be used for the cleanup. The soil sampling to determine the average background radionuclide concentrations to ultimately be used for the cleanup will be conducted prior to remediation. Background sampling will be conducted in a reference area within or outside of the property boundary that is similar to the area to be remediated.

Background reference areas will be chosen such that they are representative of the survey unit locations but are non-impacted from site operations. Representativeness shall be determined on the basis of geomorphology, geological, geochemical, and radiological, considerations.

6.6.3.2 Correlation

A correlation of the unity rule in the soil to the gamma radiation will be developed. This correlation will guide remediation and excavation. This correlation is explained in Section 6.3.2.

Remediation of the soil to meet the unity rule is described in Section 6.3.4. The final status survey reports will be the definitive source of information to describe the final impacts on the soil left by the Mill. The reports will detail how the cleanup met the Site Cleanup Criteria and show that each survey unit meets the cleanup criteria. The FSS reports will verify that the remediation has achieved the cleanup criteria.

6.6.3.3 Site Cleanup Criteria

The DCGLs for Ra-226 are set at 5 pCi/g for the surface 15 cm soil layer and 15 pCi/g for the subsurface 15 cm soil layer, respectively (hereafter referred to as "5/15") (See Attachment D for further discussion).

The DCGLs for radionuclides other than Ra-226 are derived from doses calculated for Ra-226 at 5/15 using the same exposure scenarios as were used to estimate the dose from Ra-226 at 5/15. This is referred to as the radium benchmark dose (RBD).

Generally, elevation of U-nat and Th-230 concentrations relative to Ra-226 is unexpected since the contaminated materials will either be ore (which are at or near secular equilibrium) or tailings where U-nat is reduced relative to the other uranium decay series radionuclides of interest. Possible exceptions are:

- Areas with raffinate crystals which may have higher Th-230 concentrations compared to Ra-226 concentrations
- Areas of spilled yellowcake product near the mill where U-nat may be elevated relative to Ra-226

The RBD approach was applied as described in Attachment D. The RESRAD (Version 6.5) code (Yu et al. 2001) was used to implement the RBD approach. As described in NUREG-1569 as Appendix E (NRC 2003, a Guidance document for NRC Commission Staff on the Radium Benchmark Dose Approach), NRC considers the RESRAD code as an acceptable code for application of the Ra-226 benchmark dose approach. In brief, radionuclides at their respective DCGLs result in the same benchmark dose as the Ra-226 DCGL.

The DCGLs for the radionuclides of interest for the surface and subsurface layers were calculated and are provided in Table 6.2. The scenario is for a rancher with the doses determined using the RESRAD Version 6.5 model. The default RESRAD dietary and inhalation data which apply for the adult are carefully selected from literature and are already considered to represent conservative parameter values. Details on the calculation of DCGL's are provided in Attachment D.

Table 6.2 - DCGL above background

DCGL (pCi/gram) above background		
Radionuclide	**Surface**	**Subsurface**
Ra-226	5	15
U-nat	545	2908
Th-230	46	142

Since there is more than one radionuclide of concern, the criteria for unrestricted use is applied using the unity rule such that the RBD is never exceeded.

In the equations below, the numerator is determined by subtracting the local background from the sample analysis following remediation. It is possible that the background may vary between survey units due to variation in soil types.

The unity rules are:

For surface soil:

$$\frac{A\ (pCi/g\ Ra226)}{5\ (pCi/g)} + \frac{B\ (pCi/g\ Unat)}{545\ (pCi/g)} + \frac{C\ (pCi/g\ \ Th230)}{46\ (pCi/g)} \leq 1$$

For subsurface soil:

$$\frac{A\ (pCi/g\ \ Ra226)}{15\ (pCi/g)} + \frac{B\ (pCi/g\ \ Unat)}{2908\ (pCi/g)} + \frac{C\ (pCi/g\ Th230)}{142\ (pCi/g)} \leq 1$$

MARSSIM requires that the median concentration in a survey unit be demonstrably lower than the $DCGL_W$ following remediation. This is accomplished with a WRS test between soil concentrations in the survey unit and appropriate background reference locations. For the WRS test, the actual concentrations are used for the survey unit rather than using the incremental concentrations, discussed previously in Section 6.4.2.

6.6.3.4 Gamma Radiation Surveys

Gamma radiation surveys will be conducted with a GPS-integrated system using 2-inch by 2-inch sodium iodide (NaI) detectors or the equivalent. Statistical correlations will be developed between the radiological soil sample analysis and the gamma radiation count rate. See Section 6.4.2 for the method for development and use of the gamma radiation correlation.

With the GPS-integrated method, high density gamma radiation scanning surveys will be done using the Ludlum 44-10 detectors at a height of 18 inches above the ground. The surveyor speed will be approximately 0.5 m/s.

For Class 1 survey units, transects will be 5 m apart and gamma radiation scanning surveys will continue up to 20 m outside the excavation with averages calculated on each 10-m by 10-m block. Class 1 survey units will scanned at a density to ensure that 95 percent of the 10-m by 10-m blocks have at least 20 gamma radiation measurements for blocks in and adjacent to the excavation areas with measurements in at least three of the four quadrants of the 10-m by 10-m block.

The remainder of the survey area outside the remediation area will be classified as Class 2 and will be surveyed at 10 m transects. The requirement for the remainder of the survey area, Class 2, will be that 95 percent of the blocks have at least 10 gamma radiation measurements.

The Class 3 area will include the buffer areas outside the area of contamination, and this area will be surveyed with planned transects of 50 m. Twenty percent or more of the 10-m by 10-m blocks will have at least 10 gamma radiation measurements.

The mean, median, and standard deviation of the 10-m by 10-m averages will be calculated by survey unit for data logged during the scanning surveys.

6.6.3.5 Gamma Radiation Guideline Level

The average gamma radiation count rate will be established over the 10-m by 10-m blocks. A correlation will be established between the gamma radiation level and the unity rule using co-located gamma radiation and soil concentration measurements. The gamma radiation guideline value will be the gamma radiation counts that equate to 0.8 (80 percent of unity rule) from the correlation equation. Locations where the gamma radiation guideline is exceeded will have additional gamma radiation surveys and potentially additional excavation before verification sampling.

6.6.3.6 Selection of Verification Samples

Following completion of excavation, if necessary, verification sampling will be carried out for each survey unit to allow a WRS test with background samples to confirm that the compliance criteria has been met. Ten sampling blocks will be determined from a random sampling approach for each survey unit. Following the final status gamma radiation survey, a minimum of 15 blocks in the survey unit will be measured to confirm the gamma radiation guideline level. For these 15 samples, the five 10- by 10-m blocks with the highest average gamma radiation will be sampled along with another 10 sample blocks randomly selected from the area.

The soil samples from the 10 randomly selected locations will be assessed to determine if the mean concentration in the survey unit is statistically below the unity rule with an alpha error of 0.05 using the MARSSIM WRS test.

The number of samples may be increased per Section 6.6.8.

6.6.3.7 Revision of Correlation

The verification sample measurements (soil analysis and mean gamma radiation counts) will be compared to the correlation to determine if the correlation is statistically valid. The correlation will be updated with the verification measurements if there is less than a 95 percent probability (p-value of 0.05) that the random verification data is less than $DCGL_W$. Verification measurements (soil sample and mean gamma radiation counts) will be taken with the same method as the correlation measurements.

6.6.3.7.1 Reporting

For each survey unit, the following will be reported:

1. Number of blocks remediated during remediation phase.
2. Number of blocks with subsequent remediation initiated by gamma radiation measurement.
3. Gamma radiation coverage compliance (i.e. percentage of blocks meeting number of measurement criteria).
4. Mean gamma radiation level averaged over the 10-m by 10-m blocks.
5. Mean and range of predicted unity rules based on gamma radiation survey.
6. Mean and range of measured unity rules based on verification sampling.

6.6.3.8 Field Data

The objectives of the survey and sampling activities are to identify the concentrations of residual radioactive material in the survey units so that the unity rule can be evaluated. This information will allow a determination of whether a survey unit is likely to be suitable for release. The average soil concentrations will be evaluated to verify that each radiological $DCGL_W$ is met.

6.6.4 Define the Study Boundaries

The soil in the restricted area will be surveyed for radiological contamination of U-nat, Th-230, and Ra-226. This does not include the tailings cells and unrestricted areas. Survey units will be established in the unrestricted area if, during the survey of the restricted area, contamination is found at the boundary of the restricted area or if there is reason to believe contamination is present in the unrestricted area.

6.6.5 Develop the Decision Rules/Analytical Approach

If soils exhibit widespread contamination above the $DCGL_W$, then removal of the soil will be necessary or the EMC process will need to be followed to ensure that areas of contamination will not exceed the $DCGL_W$ following excavation.

6.6.6 Define Acceptable Decision Errors

6.6.6.1 Statistical Tests

The WRS test will be used to compare background reference areas to survey units in the MARSSIM framework for the FSS reporting. The WRS test is a nonparametric test used to test for a difference in values between two populations; that is, one data population is hypothesized to consist of higher average values than the other data population.

MARSSIM suggests using the WRS test in cases where the contaminant is present in background at a significant fraction of the $DCGL_W$. Since the DCGL is 5 pCi/g for Ra-226 and the background is in the order of 1 pCi/g or more for Ra-226, the WRS test is the preferred test.

The soil concentrations from the 10 randomly selected locations as defined in Section 6.6.3.6 will be assessed with the WRS test to determine if the median concentration in the survey unit is statistically below the unity rule with an alpha error of 0.05 using the MARSSIM WRS test.

6.6.6.2 Hypothesis

The decisions necessary to determine compliance with the soil cleanup criteria are based on precise statistical statements called hypotheses, which are tested using the data from the survey unit.

<u>Null Hypotheses</u> - The situation that is presumed to exist is expressed as the null hypothesis (H_0), which states "*the median concentration in the survey unit exceeds the median concentration in the background reference area by more than the DCGL.*"

<u>Alternative Hypotheses</u> - For a given H_0, there is a specified alternative hypothesis (H_a), which is an expression of what is believed to be the situation if the null hypothesis is not true. The H_a states

"*the median concentration in the survey unit does not exceed the median concentration in the background reference area by more than the DCGL.*"

These hypotheses were chosen for the following two reasons: (1) the burden of proof is placed on the H_A and, (2) the survey unit will not be released until proven to meet the cleanup criterion. In order to pass the WRS using the above H_0, the median concentration of the systematic samples in the survey unit must be less than the $DCGL_W$ above background.

6.6.6.3 Error Types

Decision errors help to determine the number of samples required. Generally, more samples are required to generate lower decision errors (i.e., the fewer samples, the larger the uncertainty).

The statistical acceptability decisions are designed to avoid two kinds of errors:

- Releasing a survey unit which requires additional remediation
- Remediating a survey unit which is already below the $DCGL_W$

Two possible error types are associated with such decisions, Type I and Type II, which are described below.

Type I – which is also referred to as a false positive, occurs when H_0 is rejected when it is actually true. The probability of a Type I error is usually denoted by α. This error could result in higher potential doses to future site occupants than prescribed by the dose-based criterion. The maximum Type I error rate has been set at $\alpha = 0.05$ (there is less than 5 percent chance of error).

Type II - which is referred to as a false negative, occurs when H_0 is not rejected when it is actually false. The probability of a Type II error is usually denoted by β. Consequences of Type II errors include unnecessary remediation expense and project delays. The Type II error rate has been set at $\beta=0.10$ (there is less than 10 percent chance of error).

Statistical correlations will be developed between the unity rule and the gamma radiation measurements. The unity rule will be determined from measurement data for incremental concentrations at each sample location. The correlation between the unity rule and the gamma radiation measurement at the sample location will produce a prediction equation. MARSSIM requires that the mean concentration in a survey unit be demonstrably lower than criteria following remediation but does not require all sampling units, in this case the 10-m by 10-m areas, to be lower than the criteria. The precision goal for the relationship will be that the mean prediction uncertainty for the survey unit will be +/- 0.2 when the predicted unity rule is equal to “1”.

Protocols will be in place to ensure decision errors are kept to a minimum. For example, instrument quality assurance checks will be required and minimum detectable concentrations (MDCs) will be met.

The gamma radiation survey will be limited by the MDC for the 2-inch x 2-inch sodium iodide (NaI) detector which is approximately 104 Bq/Kg (2.8 pCi/gram) for Ra-226, MARSSIM Table 6.7. This MDC is dependent on the background which may raise or lower the MDC (NRC, 2000).

Table 6.3. Reported MDC’s from MARSSIM Table 6.7

Nuclide	MDC (Bq/kg)	MDC (pCi/gram)
U-Nat	2960	80
Th-230	78,400	2100
Ra-226 (with decay products in equilibrium)	104	2.8

6.6.7 Relative Shift and Number of Samples

The target decision errors are 0.05 and 0.10 for α andβ, respectively. The major contributor to the unity rule is Ra-226 since the criterion is much lower for Ra-226 compared to U-nat and Th-230. The lower bound of the gray region (LBGR) has been set to 0.8 as Ra-226 has a typical concentration that is only about 25 percent of the LBGR and the uncertainty will likely be of this order.

The preliminary estimate is that a relative shift of 2.0 based on the LBGR of 0.8 and an uncertainty of twice the background concentration. Using Table 5.3 of MARSSIM (NRC, 2000), the required number of samples is 8.

Should any area exceed the $DCGL_{EMC}$ or large areas exceed the $DCGL_{W}$, remediation of the affected areas would be completed prior to resampling.

6.6.8 Optimize the Design

Initially, gamma radiation scans will be conducted in the restricted areas of the Mill site. The data from these scans will be reviewed to determine the location of any hotspots. These hotspot locations will be sampled to determine the activity concentrations of U-nat, Th-230, and Ra-226. A prediction equation of the unity rule will provide the basis for scanning large areas effectively to direct focused remediation and to ensure that the cleanup criterion is met.

The statistical test (WRS test) could fail to show that the mean is below the criterion due to the initial number of verification samples, since there may be insufficient samples to achieve the desired decision error rates given the characteristics of the survey unit. In cases where data suggest that the concentration is below the criterion (e.g., the mean bases), additional samples would reduce the decision error and potentially allow the survey unit to pass. In this case, the mean and variability of the 10 randomly selected measurements will be used to determine MARSSIM's relative shift with the lower bound of the gray region equal to 0.8 of the unity rule. The α error will be set to 5 percent and the β error set to 10 percent to determine the required total number of samples. These samples would be collected and the WRS repeated on the larger data set.

6.7 Soil Sampling

6.7.1 Laboratory Approval

All samples will be analyzed for radionuclide activity concentration (pCi/g). All analyses will be performed by a DWMRC-approved/certified laboratory and a DOE-certified, or National Environmental Laboratory Accreditation Program (NELAP)-certified laboratory. The laboratory will analyze method blanks, matrix spike samples, laboratory control samples and replicates. Typical required detection levels will be less than or equal to one tenth of the DCGL for each radionuclide.

6.7.2 Data Validation

Laboratory analytical results from the final status survey will be validated and will be reviewed by the data validator for the following:

- Data completeness/sample integrity
- Holding times
- Calibration
- Alpha spectroscopy tracer analysis
- Laboratory and field blanks
- Laboratory control samples
- Laboratory and field duplicates
- Alpha spectroscopy matrix spikes
- Quantitation and detection limits
- Alpha spectroscopy chemical separation specificity
- Gamma radiation spectroscopy target radionuclide list identification
- Secular equilibrium verification, and result verification

Review of these parameters checks the quality of the data with respect to:

- Precision – which is a measure of the reproducibility of an analysis under a given set of conditions. Precision will be evaluated through a review of field duplicate and laboratory duplicate samples.

- Accuracy – which is a measure of the bias that exists in a measurement system. Accuracy will be evaluated through a review of laboratory control samples, matrix spike samples, method blanks, and tracer recoveries.

- Representativeness – which is a measure of the degree to which the sampling data accurately and precisely represent site conditions. Representativeness will be evaluated through a review of raw data and through a comparison of whether the proposed scoping survey was implemented.

- Comparability – which is a measure of the degree of confidence with which two data sets can be compared to each other. Comparability will be evaluated through an assessment of whether appropriate and acceptable analytical methods were used.

- Completeness – which is a measure of the amount of valid data obtained.

6.8 Employee Health and Safety

Programs currently in place for monitoring of exposures to employees will remain in effect throughout the time period during which tailings cell reclamation, mill decommissioning and clean up of windblown contamination are conducted. This will include personal monitoring and the ongoing bioassay program. Access control will be maintained at the Restricted Area boundary to ensure employees and equipment are released from the site in accordance with the current License conditions. In general, no changes to the existing programs are expected and reclamation activities are not expected to increase exposure potential beyond current levels.

6.9 Environment Monitoring

Existing environmental monitoring programs will continue during the time period in which reclamation and decommissioning is conducted. This includes monitoring of surface and groundwater, airborne particulates, radon, soils and vegetation according to the existing License conditions. In general, no changes to the existing programs are expected and reclamation activities are not expected to increase exposure potential beyond current levels.

6.10 Quality Assurance

In general, the QA/QC Plan details the Owner's organizational structure and responsibilities, personnel qualifications, operating procedures and instructions, record keeping and document control, sampling procedures and outside laboratory testing.

7.0 MATERIAL DISPOSAL

7.1 General

This section outlines work associated with placement of materials in the disposal cell area within Cell 1 (Cell 1 Disposal Area) and tailings cells (Cells 2 through 4).

7.2 Materials Description

The types of materials to be disposed of are outlined below.

7.2.1 Raffinate Crystals

After the residual liquid in Cell 1 has been evaporated, the raffinate crystals from Cell 1 will be excavated and disposed in one of the tailings disposal cells. The crystals are likely to have granular consistency, with larger crystal masses that may require breaking down for loading and transport (using the loading equipment).

7.2.2 Synthetic Liner

The existing PVC liner in Cell 1 will be removed and disposed of in one of the tailings disposal cells.

7.2.3 Contaminated Soils

During remediation, soils located in and around the Mill site that exceed the soil cleanup guideline value will be placed in one of the tailings disposal cells. Soils excavated from Cell 1 to meet design grades or exceed the soil cleanup guideline value shall be placed in one of the tailings disposal cells.

7.2.4 Mill Debris

The Mill debris will include equipment, such as tankage and piping, agitation equipment, process control instrumentation and switchgear, and contaminated structures (including concrete structures and foundations). Mill debris will be placed in the Cell 1 Disposal Area.

7.3 Work Description

Materials to be disposed in the cells will be spread over the working surface as much as possible to provide relatively uniform settlement and consolidation. In the disposal cell, a minimum of one foot of soil will be placed over the clay liner prior to placing any debris.

7.3.1 Raffinate Crystals

Raffinate crystals will be removed from Cell 1 and transported to the tailings cells. Placement of the crystals will be performed as a granular fill, with large-sized material broken to minus 6-inch size. Voids around large material will be filled with finer material. Actual placement procedures will be evaluated by the CQA Officer during construction as crystal materials are placed in the cells and modified with the agreement of the DWMRC.

7.3.2 Synthetic Liner

The PVC liner will be cut, folded (when necessary), removed from Cell 1, and transported to the tailings cells. The liner material will be spread as flat as practical over the designated area. After placement, the liner will be covered as soon as possible with at least one foot of soil, crystals or other materials for protection against wind uplift, as approved by the CQA Site Manager.

7.3.3 Contaminated Soils

The extent of contamination of the Mill site will be determined by gamma radiation scanning and the A correlation developed between gamma survey readings and the unity rule concentrations (Section 6). Gamma survey readings will be used to define cleanup areas and confirm cleanup. Soil sampling will be conducted to verify that the cleanup results meet soil cleanup guideline values.

Where surveys indicate the above criteria have not been achieved, the soil will be removed to meet the criteria. Soil excavated from Cell 1 will be transported to one of the tailings cells.

7.3.4 Mill Debris

Debris will be spread across the bottom of the disposal cell to avoid nesting and to reduce the volume of voids present in the disposed mass. Stockpiled soils and/or other approved materials will be placed over and into the debris in a sufficient lift thickness to fill the voids between the debris pieces. The CQA Site Manager will approve the use of materials other than stockpiled soils for filling voids.

7.3.5 Material Sizing and Preparation

Demolition debris to be placed in the Cell 1 Disposal Area will consist of equipment and structural material from facilities demolition. Demolition procedures are outlined in the Appendix B to the Reclamation Plan (Preliminary Mill Decommissioning Plan). Because of the wide variety in shape and size of demolition debris, material of odd shapes will be cut or dismantled to facilitate handling, loading, transport, and placement in the disposal cell. The maximum size of dismantled or cut materials will not exceed 20 feet in the longest dimension and a maximum volume of 30 cubic feet. Smaller dimensions may be necessary for loading, handling, hauling, and placement of material.

7.3.6 Incompressible Debris

Material that is not compressible (steel columns and beams, concrete, and other solid material) will be reduced in size for loading, hauling, and placement in the disposal cell. Incompressible debris shall be placed, oriented, or spread in a manner that minimizes void spaces below, between, and above these materials. Incompressible debris shall be placed on and covered with soils or similar materials (Section 7.2.3). Incompressible debris such as steel members shall be placed in the disposal cell with the longest dimension oriented horizontally.

Thick-walled pipe, conduit, tanks, vats, pressure vessels, and other hollow materials that cannot be crushed or dismantled shall be transported to the planned location within the disposal cell and oriented for filling and burial. The voids on the inside of the item will be filled with contaminated soil, clean fill soil, or grout (controlled low-strength material or flowable fill). Contaminated soil (Section 7.2.3) or clean fill will be placed outside of the items and compacted with standard compaction equipment (where possible) or hand-operated equipment to the compaction requirements in Section 7.4. Several lifts of compacted contaminated soil or clean fill may be necessary to fill around and cover these items.

For debris where internal voids cannot practically be filled with soil, a grouting program will be initiated to pump controlled low strength material (CLSM, flowable fill) into the voids. Debris will be grouped together and characterized as materials that will require grouting, so that a significant volume of debris can be grouted in a single action, rather than grouting individual lengths of pipe. Pipe sections could be stacked horizontally, or cut short enough to stand vertically in a safe manner. Grout will fill the voids within the grouped debris with a soil berm or trench used to contain the grout laterally around the perimeter of the selected debris.

If CLSM is required for the grouting of voids that cannot be filled with soil, the mix design for the grout will mimic, as closely as possible, the strength and hydraulic properties of the contaminated soil that will also be used for filling voids within the debris. The unconfined compressive strength of the CLSM will be between 30 and 150 psi, and unit weights will be approximately 100 to 120 pcf.

7.3.7 Compressible Debris

Materials that are compressible (such as thin-walled piping and thin-walled tanks) will be flattened or crushed in a designated staging area or in the disposal cell. Flattening or crushing will be done with a hydraulic excavator bucket or other attachments, or with a dozer or other steel-tracked equipment.

These materials shall be placed in the disposal cell and spread to form a lift with a maximum thickness of two feet. Placement shall be done in a manner resulting in materials lying flat and minimizing void spaces. Pipe shall be cut into lengths of approximately 10 feet or less for disposal. Pipe larger than 12 inches in diameter shall be longitudinally split or cut, or filled with grout.

7.3.8 Organic Debris

Organic materials (such as wood and paper) will be placed in the disposal cell in maximum lifts of 12 inches and mixed with the soil and other incompressible debris during placement to prevent pockets of organic material from being created. Organics mixed with soil for spreading will be limited to 30 percent by volume of the mixture.

7.3.9 Soils and Similar Materials

Soils and soil-like materials to be placed in the disposal cell will be from on-site areas identified by the Owner for excavation. Soil or soil-like material will be placed and compacted over each lift of debris (Section 7.2.4) or other materials in lifts not to exceed 2 feet in loose thickness and compacted prior to placement of additional lifts. Soils will also be used for interim soil cover to minimize exposure of demolition materials and other materials to air and meteoric water.

7.4 Performance Standards and Testing

7.4.1 Material Compaction – Debris Lifts

During construction, the compaction requirements for the raffinate crystals will be evaluated based on field conditions, material quantities, and compaction equipment. The compaction requirements will be determined by the CQA Site Manager and the Construction Manager or a designated representative, with the agreement of the Owner.

Each lift of debris (up to 2 feet thick) will be covered with soil (Section 7.3.9) (up to 2 feet in loose thickness). Each lift of soil or similar material will be compacted with a minimum of 6 passes with vibratory compaction equipment. The number of passes shall be confirmed with the actual compaction equipment on site with a field test section to establish a correlation between the field compaction method and 80 percent of maximum dry density for the soil, as determined by the standard Proctor test (ASTM D698).

The CQA Technicians will monitor and approve debris placement. In areas where voids are observed during placement, the Contractor shall re-excavate the area, fill any voids encountered with soil and recompact the materials, or grout the voids. The CQA Site Manager will recommend implementation of a grouting program where voids, either within a debris mass, or within a vessel, cannot be properly filled with soil using conventional equipment.

7.4.2 Material Compaction – Final Disposed Material Surface

The upper 12 inches of the final disposed material surface shall be compacted to 90 percent of the maximum dry density for the material, as determined by the standard Proctor test (ASTM D698).

7.4.3 Testing Frequency

Field density tests shall be compared with standard Proctor tests (ASTM D698 Method A or C) on the same material. Standard Proctor tests shall be conducted at a frequency of at least one test per 5,000 cubic yards of material compacted, or when material characteristics show significant variation.

Field density testing may be conducted with the sand cone test (ASTM D1556) or a nuclear density gauge (ASTM D6938, or as modified by the CQA Site Manager). Correlation of nuclear density gauge results shall be by comparison with results from sand cone test(s) and laboratory testing for water content(s) using the oven drying method (ASTM D2216) on similar material.

The frequency of the field density and moisture tests will be not less than one test per 2,000 cubic yards of compacted soil. A minimum of two tests will be taken for each day that more than 150 cubic yards of material is placed. A minimum of one test per lift and at least one test for every full shift of compaction operations will be taken.

7.4.4 Final Slope and Grades

The final disposed material surface shall have maximum side slopes of 5:1 (H:V) and a top surface sloping in the directions and grades shown on the Drawings. The side slopes and top surface shall be free from abrupt changes in grade or areas of runoff concentration. The final disposed material surface shall be compacted with approved construction equipment to form a smooth surface with uniform density for subsequent cover placement.

8.0 COVER CONSTRUCTION

8.1 General

This section outlines work associated with construction of the cell cover system. A multi-layered earthen cover will be placed over tailings Cells 2, 3 and 4A and a portion of Cell 1 used for disposal of contaminated materials (the Cell 1 Disposal Area).

8.2 Materials Description

8.2.1 Random Fill

The random fill for the interim fill, compacted cover, and growth medium layers will consist of on-site stockpiled soils from areas designated by the Owner. Random fill, except for the interim fill, shall have a maximum particle size of 6 inches, and a minimum of 10 percent passing the No. 200 sieve. Oversized material will be controlled through selective excavation at the stockpiles and through the utilization of a grader, bulldozer or other equipment to cull or break down oversized materials.

The source of these materials will be on-site stockpiles from previous cell construction activities. On-site stockpiles shall be approved for specific use by the Construction Manager and Design Engineer prior to use.

8.2.2 Organic Matter Amendment

Composted biosolids will be used to amend the physical and chemical properties of the random fill used to construct the growth medium layer (Section 8.3.7). Composted biosolids will be added to the upper 6 inches of the growth medium layer at a rate of 10 tons/acre.

8.2.3 Topsoil-Gravel Admixture

Gravel will be mixed with topsoil and placed on portions of the cover on Cells 2, 3, 4A, and 4B top surfaces (as shown on the Drawings) as the erosion protection layer. Topsoil-gravel admixture material shall be shall be free from roots, branches, rubbish, and debris.

The gravel portion of the topsoil-gravel admixture will consist of granular materials from approved off-site areas. The gravel portion of the topsoil-gravel admixture shall have a maximum particle size of 1 inch.

The topsoil portion of the topsoil-gravel admixture will consist of select material from the on-site topsoil borrow area (Section 3.4). The mixture shall be 25 percent gravel by weight.

8.2.4 Riprap

Riprap will be placed along the toe of the disposal cell and the tailings cells (as shown on the Drawings). Riprap will consist of granular materials from approved off-site sources. Riprap shall be shall be a screened product, free from roots, branches, rubbish, and debris.

Riprap shall meet NRC long-term durability requirements (a rock quality designation of 65 or more; Johnson, 2002). For a rock quality designation of 70 or higher, the particle-size specifications below shall be used. If actual rock quality designation is between 65 and 69, oversizing will be required.

Designated gradations for the riprap will be as specified on the Drawings. Riprap will be imported from off-site.

- Side Slope riprap shall have a minimum D_{50} as listed below and a minimum layer thickness of 1.5 times the D_{50} or the D_{100} of the riprap, whichever is greater:
    - 1.7 in. for non-accumulating flow side slopes
    - 5.3 in. for Cell 4A and Cell 4B southern side slopes
    - 5.3 in. for Cell 1 Disposal Area side slope
- Riprap used in the rock aprons shall have a minimum D_{50} as listed below and a minimum layer thickness of 1.5 times the D_{50} or the D_{100} of the riprap, whichever is greater
    - 3.4 in. for Rock Apron A

- 10.6 in. for Rock Apron B
- 9.0 in. for Rock Apron C

8.2.5 Filter Material

Filter material shall be shall be free from roots, branches, rubbish, and debris. The filter material shall meet the gradation specifications in Table 8.1.

Table 8.1 – Filter Material Gradation

Sieve Size	Percent Passing, By Weight
3-inch	100
No. 4	70-100
No. 20	40-60
No. 200	0-5

8.2.6 Topsoil

Topsoil will consist of select material from the designated, on-site topsoil borrow area (Section 3.4).

8.3 Work Description

The Contractor will place cover materials based on a schedule determined by the Owner and the Owner's analysis of settlement data, piezometer data and equipment mobility considerations. Settlement monitoring points will be established and monitored in accordance with Sections 8.3.1 to 8.3.3 and the Settlement Monitoring Plan approved by DWMRC for the site.

Cover construction shall minimize lenses, pockets, or layers of material differing substantially in texture, gradation or moisture content from the surrounding material. Oversized material will be controlled through selective excavation of stockpiled material, observation of placement by a qualified individual with authority to stop work and reject material being placed and by culling oversized material from the fill.

If the compacted surface of any layer of fill is too dry or smooth to bond properly with the layer of material to be placed thereon, it will be moistened and/or reworked with suitable equipment to a sufficient depth to provide relatively uniform moisture content and a satisfactory bonding surface before the next succeeding layer of fill is placed. If the compacted surface of any layer of fill in-place is too wet, due to precipitation, for proper compaction of the fill material to be placed thereon, the material will be reworked to reduce the moisture content to the specified range and recompacted.

No material will be placed when either the material being compacted, or the underlying material, is frozen or when ambient temperatures do not permit the placement or compaction of the materials to the specified density, without developing frost lenses in the fill.

8.3.1 Monitoring Interim Cover Settlement

The existing settlement monitoring points located within tailings disposal cells will be maintained by extending them through additional fill placement. For areas without settlement monitoring points, settlement monitoring points will be installed to monitor settlement of the interim cover surface and will be constructed as specified in the DWMRC approved Settlement Monitoring Plan. Settlement data will be collected and analyzed; and the reclamation techniques and schedule will be adjusted accordingly.

8.3.2 Monitoring Final Cover Settlement

After placement of final cover material, settlement plates will be extended or will be installed to monitor settlement of the final cover surface. The settlement plates will be constructed as specified in the DWMRC approved Settlement Monitoring Plan.

8.3.3 Monitoring Settlement Points

Settlement monument placement and data collection will be made in accordance with the DWMRC approved Settlement Monitoring Plan.

8.3.4 Interim Fill Layer

The interim fill layer will have a minimum thickness of 2.5 feet and will be placed over the tailings surface to form a stable working platform for subsequent controlled fill placement. This interim fill layer will be placed by pushing random fill material across the tailings such that the underlying tailings are displaced as little as possible. Interim fill will be placed in lifts of 12-inch maximum loose thickness to form a uniform subsoil layer for the cover system. A rough surface will be maintained on the surface of each lift.

8.3.5 Compacted Cover Layer

The compacted cover layer shall be constructed of random fill placed in lifts with a maximum loose thickness of 12 inches to form a continuous layer with a total minimum compacted layer thickness of 36 to 48 inches, as indicated in the Drawings. A rough surface will be maintained on the surface of each lift.

8.3.6 Growth Medium Layer

The growth medium layer shall be constructed of random fill placed to a minimum of 42 inches thick, above the compacted cover layer in lifts of 18-inch maximum loose thickness. If oversized material is observed during the excavation of fill material, it will be removed, as far as practicable, before it is placed in the fill. A rough surface will be maintained on the surface of all but the uppermost lift.

8.3.7 Organic Matter Amendment

Composted biosolids will be applied prior to the placement of the erosion protection layer (topsoil or the topsoil-gravel admixture). Composted biosolids will be uniformly spread over the surface of the growth medium layer and mixed to a depth of 6 inches.

8.3.8 Erosion Protection Layer: Topsoil-Gravel Admixture

The topsoil and the gravel admixture shall be 75 percent topsoil - 25 percent gravel admixture (by weight). The mixture shall be prepared (mixed) prior to transport to the placement areas. Gradation samples will be collected at the point of placement to verify the mixture's content. The

CQA Site manager will approve the Contractor's proposed method of mixing based on the gradation results during initial placement.

The mixture shall be placed in one loose lift to form a uniform layer with a final thickness of 6 inches on the slope surfaces of the disposal cell (shown on the Drawings). The topsoil-gravel admixture shall be spread with tracked equipment.

The erosion protection layer will not be amended for organic matter or nutrients to avoid the stimulation of undesirable weedy species.

Following placement of the topsoil-gravel admixture erosion protection layer, the area shall be harrowed to reduce any compaction that may have occurred during placement of the cover and to create an uneven surface for optimum seedbed conditions.

8.3.9 Erosion Protection Layer: Topsoil

Topsoil (Section 8.2.6) shall be placed in one loose lift to form a uniform layer with a final thickness of 6 inches on the top and side slope surfaces of the disposal cell (shown on the Drawings). The topsoil shall be spread with tracked equipment.

The erosion protection layer will not be amended for organic matter or nutrients to avoid the stimulation of undesirable weedy species.

Following placement of the topsoil layer, the area will be harrowed to reduce any compaction that may have occurred during placement of the cover and to create an uneven surface for optimum seedbed conditions.

8.3.10 Riprap and Filter Material Placement

The side slopes of the reclaimed cover will be protected by rock surfacing. Riprap (Section 8.2.4) and filter material (Section 8.2.5) shall be placed in one or more lifts to the depths outlined in the Drawings and using the methods outlined below. The Drawings show the location of riprap with the size and thickness requirements for the various side slopes and aprons.

Filter material and riprap shall be handled, loaded, transported, stockpiled, and placed in a manner that minimizes segregation. Riprap and filter material shall be placed in or near its final location by dumping, then spread with a small dozer, the bucket of a trackhoe, or other suitable equipment. Riprap and filter material shall be placed and spread in a manner that minimizes displacement of underlying cover soils, natural soils, or filter material. Each layer of riprap and filter material shall be track-walked with a small dozer, tamped with the bucket of a trackhoe, or densified by other approved methods.

Placement of the riprap will avoid accumulation of riprap sizes less than the minimum D_{50} size and nesting of the larger sized rock. The riprap layer will be compacted by at least two passes by a dozer, tamping with the bucket of a trackhoe, or equivalent methods in order to key in the rock particles for stability. The completed layer of filter material shall be well-graded in particle-size distribution and free from pockets of smaller material and free from large voids or loose areas.

8.4 Performance Standard and Testing

8.4.1 Compacted Cover Layer Testing

Each lift of the compacted cover layer shall be compacted to at least 95 percent of the maximum dry density for the material, as determined by the standard Proctor test (ASTM D698). Water contents shall be adjusted, as needed, to meet the density requirements.

Material specifications for the random fill material shall be confirmed by gradation testing conducted by approved personnel. Testing shall consist of No. 200 sieve wash and particle-size distribution testing (ASTM D422) at a frequency of at least one test per 2,000 cubic yards of fill placed, or when material characteristics show a significant variation.

Checking of compaction shall consist of a minimum of one field density test per 500 cubic yards of material compacted. A minimum of two tests shall be taken for each day that more than 150 cubic yards of material is placed. A minimum of one test per lift and at least one test for every full shift of compaction operations will be taken.

Field density tests shall be compared with standard Proctor tests (ASTM D698 Method A or C) on the same material. Standard Proctor tests shall be conducted at a frequency of at least one test per

5,000 cubic yards of material compacted, or when material characteristics show significant variation.

Field density testing may be conducted with the sand cone test (ASTM D1556) or a nuclear density gauge (ASTM D6938, or as modified by the CQA Site Manager). Correlation of nuclear density gauge results shall be by comparison with results from sand cone test(s) and laboratory testing for water content(s) using the oven drying method (ASTM D2216) on similar material.

8.4.2 Growth Medium Layer Testing

Each lift of the growth medium layer shall be compacted to at least 85 percent of the maximum dry density for the material, as determined by the standard Proctor test (ASTM D698). Water contents shall be adjusted, as needed, to meet the density requirements.

Material specifications for the random fill for water storage layer shall be confirmed by gradation testing conducted by approved personnel. Testing shall consist of No. 200 sieve wash and particle-size distribution testing (ASTM D422) at a frequency of at least one test per 2,000 cubic yards of fill placed, or when material characteristics show a significant variation.

The frequency of the field density tests will be not less than one test per 2,000 cubic yards of compacted fill. A minimum of two tests will be taken for each day that more than 150 cubic yards of material is placed. A minimum of one test per lift and at least one test for every full shift of compaction operations will be taken.

Field density tests shall be compared with standard Proctor tests (ASTM D698 Method A or C) on the same material. Standard Proctor tests shall be conducted at a frequency of at least one test per 10,000 cubic yards of material compacted, or when material characteristics show significant variation.

Field density testing may be conducted with the sand cone test (ASTM D1556) or a nuclear density gauge (ASTM D6938, or as modified by the CQA Site Manager). Correlation of nuclear density gauge results shall be by comparison with results from sand cone test(s) and laboratory testing for water content(s) using the oven drying method (ASTM D2216) on similar material.

8.4.3 Topsoil-Gravel Admixture Testing

The gradation specifications for the topsoil-gravel admixture (Section 8.2.3) shall be confirmed by gradation testing, on samples collected from the point of placement (on the top deck). Testing shall consist of particle-size distribution testing (ASTM D422) at a frequency of at least one test per 2,000 cubic yards of mixture placed, or when the characteristics of the mixture show a significant variation. The CQA Site Manager may choose to increase the frequency of testing at the beginning of placement to evaluate the mixing method proposed by the Contractor.

Topsoil-gravel admixture thickness will be controlled through the establishment of grade stakes placed on a 200 x 200 foot grid on the top of the cells and by a 100 x 100 foot grid on the cell slopes. Physical checks of topsoil-gravel admixture depth will be accomplished through the use of hand dug test pits at the center of each grid in addition to monitoring the depth indicated on the grade stakes.

8.4.4 Riprap Testing

Material specifications for the riprap shall be confirmed by gradation testing conducted by the CQA Technician. Testing shall consist of particle-size distribution testing (ASTM D422) at a frequency of at least one test per 2,000 cubic yards of rock delivered to the site, or when rock characteristics show a significant variation.

Rock layer thickness will be controlled through the establishment of grade stakes placed on a 200 x 200 foot grid on the top of the cells and by a 100 x 100 foot grid on the cell slopes. Physical checks of riprap depth will be accomplished through the use of hand dug test pits at the center of each grid in addition to monitoring the depth indicated on the grade stakes.

The durability of the riprap shall be verified by durability tests outlined in Section 8.4.7.

8.4.5 Filter Material Testing

Material specifications for filter material (Section 8.2.5) shall be confirmed by gradation testing conducted by CQA Technician. Testing shall consist of No. 200 sieve wash and maximum particle size testing (ASTM D422) at a frequency of at least one test per 10,000 cubic yards of fill placed, or when material characteristics show a significant variation.

Filter layer thickness will be established during construction with grade stakes placed on a grid or centerline and offset pattern and layer thickness marks on each grade stake. The minimum thickness of the layer will be verified by spot checking of layer thickness by hand excavation in selected locations.

8.4.6 Rock Durability Testing

For riprap materials, each load of material will be visually checked against standard piles for gradation prior to transport to the tailings piles. Prior to delivery of any riprap materials to the site, rock durability tests will be performed for each gradation to be used. Test series for riprap durability will include specific gravity, absorption, sodium soundness and LA abrasion. During construction, additional test series and gradations will be performed for each type of riprap when approximately one-third (1/3) and two-thirds (2/3) of the total volume of each type have been produced or delivered. For any type of riprap where the volume is greater than 30,000 cubic yards, a test series and gradations will be performed for each additional 10,000 cubic yards of riprap produced or delivered.

8.5 Surface Slopes and Grades

The final cover surface shall have maximum side slopes of 5:1 (H:V) and a top surface sloping in the direction and grade shown on the Drawings. The side slopes and top surface shall be free from abrupt changes in grade or areas of runoff concentration. The perimeter apron at the toe of the side slopes shall have the dimensions as shown on the Drawings.

8.6 Grading Tolerances

The completed cover surface shall be constructed to within 1.0 foot (horizontally) of the lines as designed, and within 0.1 foot (vertically) of the elevations as designed. The final surface of the subsoil zone shall be smoothed to avoid abrupt changes in surface grade. The layer thicknesses shall meet the required minimum thicknesses.

The completed riprap shall be placed to within 5.0 foot (horizontally) of the layout as designed, and within 0.5 foot (vertically) of the elevations as designed. The rock layer thicknesses shall meet the minimum requirements.

9.0 REVEGETATION

9.1 General

Following topsoil placement, the cover surface and other areas disturbed during reclamation work will be revegetated. This section outlines the requirements for vegetation establishment where required. This section may be revised as necessary based on field requirements and soil nutrient analyses at the time of revegetation.

9.2 Materials Description

The soil amendments, seed mixture, and erosion control materials for revegetation are outlined below. Submittals for each of the following products shall be provided to the Owner for approval prior to use of such products.

9.2.1 Soil Amendments

The proposed application rate may be adjusted up or down based on soil chemical analysis that is conducted prior to placement of the water storage layer.

Composted biosolids shall be added at a rate of 10 tons/acre and uniformly spread over the surface of the water storage layer and mixed to a depth of 15 cm. This treatment will be applied after the water storage layer is in-place and before placement of the erosion protection layer.

9.2.2 Seed Mix

Species selection for the seed mixture was based on native vegetation found in the area as well as soil and climatic conditions of the Mill site. Changes to the seed mixture will be as approved by the Owner. The seed mixture in Table 9.1 shall be used on all seeded areas.

Table 9.1. Species and seeding rates proposed for Mill site.

Scientific Name	Common Name	Varietal Name	Native/ Introduced	Seeding Rate (lbs PLS/acre)†	Seeding Rate (# seeds/ft^2)
Grasses					
Pascopyrum smithii	Western wheatgrass	Arriba	Native	3.0	7.9
Pseudoroegneria spicata	Bluebunch wheatgrass	Goldar	Native	3.0	9.6
Elymus trachycaulus	Slender wheatgrass	San Luis	Native	2.0	6.2
Elymus lanceolatus	Streambank wheatgrass	Sodar	Native	2.0	7.3
Elymus elymoides	Squirreltail bottlebrush	Toe Jam	Native	2.0	8.8
Thinopyrum intermedium	Pubescent wheatgrass	Luna	Introduced‡	1.0	1.8
Achnatherum hymenoides	Indian ricegrass	Paloma	Native	4.0	14.7
Poa secunda	Sandberg bluegrass	Canbar	Native	0.5	11.4
Festuca ovina	Sheep fescue	Covar	Introduced‡	1.0	11.5
Bouteloua gracilis	Blue grama	Hachita	Native	1.0	16.5
Hilaria jamesii	Galleta	Viva	Native	2.0	7.3
Forbs					
Achillea millefolium, variety *occidentalis*	Common yarrow	VNS*	Native	0.5	32
Artemisia ludoviciana	White sage	VNS	Native	0.5	45
Shrubs					
Atriplex canescens	Fourwing saltbush	Wytana	Native	3.0	3.4
Ericameria nauseosa	Rubber rabbitbrush	VNS	Native	0.5	4.6
Total				26.5	188

†Seeding rate is for broadcast seed and presented as pounds of pure live seed per acre (lbs PLS/acre).
‡Introduced refers to species that have been 'introduced' from another geographic region, typically outside of North America. Also referred to as 'exotic' species.
*VNS=Variety Not Specified and seed source will be from sites that are climatically similar to White Mesa.

Seed shall be purchased as pounds of pure live seed and will be certified by the Utah State Department of Agriculture and Food. Certification will verify that the seed is correctly identified and genetically pure. Once the seed is obtained, seed labels will be checked to determine the percent PLS and the date that the seed was tested for percent purity and percent germination. If the test date is greater than 6 months old, the seed will be tested again before being accepted.

9.2.3 Erosion Control Materials

Wood fiber mulch will consist of specially prepared wood fibers and will not be produced from recycled material such as sawdust, paper, cardboard, or residue from pulp and paper plants. The fibers will be dyed an appropriate color, with non-toxic, water-soluble dye to facilitate visual metering during application. Wood-fiber mulch will be supplied in packages and each package will be marked by the manufacturer to show the air-dry weight.

A tackifier will be used with the wood-fiber mulch to improve adhesion. The tackifier will be a biodegradable organic formulation processed specifically for the adhesive binding of mulch. In addition, the tackifier will uniformly disperse when mixed with water and will not be detrimental to the homogeneous properties of the mulch slurry.

9.3 Work Description

Revegetation efforts shall be directed at all reclaimed and disturbed areas. The goal of the revegetation plan is to ensure that a self-sustaining vegetative community is established.

9.4 Soil Amendment Application

Following final placement and grading of the frost barrier layer, amendments will be applied as discussed in Section 9.2.1. Inorganic sources of nitrogen, phosphorus, and potassium will not be applied to the soil because composted biosolids will provide all the macronutrients required for long-term sustainability.

9.5 Growth Zone Preparation

A favorable seedbed shall be prepared on the topsoil layer or topsoil-rock mixture, prior to seeding operations. The soil shall be loose and friable so as to maximize contact with the seed. The soil will be tilled, following site contours with a disc or harrow (or similar approved equipment) to a maximum depth of 6 inches. The depth of valleys and the height of ridges caused by the final tillage operations are not to exceed 3 inches.

9.6 Seed Application

Seeding will follow the application of soil amendments and seedbed preparation, by broadcast spreading method. This procedure will use a centrifugal type broadcaster (or similar implement), also called an end gate seeder. The broadcasters will have a minimum effective spreading width of 20 feet. Seed will be applied in two separate passes. One-half of the seed will be spread in one direction and the other half of seed will be spread in a perpendicular direction. This will ensure that seed distribution across the site is highly uniform and also provide the opportunity to adjust the seeding rate if the specified rate is not being achieved. Seeding will not occur if wind speeds exceed 10 mph.

Immediately following seeding, the area will be lightly harrowed to provide seed coverage and to maximize seed-soil contact. Broadcast seed shall be harrowed into the soil to a depth of 0.25 to 0.75 inches.

Seeding will take place as soon as practical after the cover system is in place. Successful seeding in southeastern Utah can occur either in late fall (e.g. October) as a dormant seeding, with germination and establishment occurring the following spring or can be conducted in June, prior to the summer monsoon season. Timing for seeding will depend upon the construction schedule for the cover system.

9.7 Erosion Control Material Application

Mulch will be applied immediately following seeding. A weed-free, wood-fiber mulch shall be applied to the seeded area at a minimum rate of 1.5 tons/acre. The wood-fiber mulch will be applied by means of hydraulic equipment that utilizes water as the carrying agent. A continuous agitator action, that keeps the mulching material and approved additives in uniform suspension, will be maintained throughout the distribution cycle.

The pump pressure will be capable of maintaining a continuous non-fluctuating stream of slurry. The slurry distribution lines will be large enough to prevent stoppage and the discharge line will be equipped with a set of hydraulic spray nozzles that will provide even distribution of the mulch slurry to the seedbed. Mulching will not be done in the presence of free surface water resulting from rains, melting snow, or other causes. Tackifier may be added either during the manufacturing of the mulch or incorporated during mulch application.

9.8 Performance Standard and Testing

The following section describes performance-based criteria for successful revegetation.

9.8.1 Seeding Rates

Prior to seeding, a known area will be covered with a tarp and seed will be distributed using the broadcaster and simulating conditions that would exist under actual seeding conditions. Seed will then be collected and weighed to determine actual seeding rate in terms of pounds per acre. This process will be repeated until the specified seeding rate is obtained.

During the seeding process, the seeding rate will be verified at least once by comparing pounds of seed applied to the size of the area seeded.

9.8.2 Erosion Control

The cover shall be inspected two times per year for eroded areas. Any area that has experienced erosion shall be backfilled and reseeded. Erosion control materials shall also be reapplied over reseeded areas.

9.8.3 Weed Control

Weed management will be conducted on the Mill site by identifying the presence of any noxious weeds during annual vegetation surveys and developing a weed control plan that is specific to the species that are present (Table 9.2). Noxious weed control is species-dependent and both method and timing will vary from species to species.

Table 9.2. Noxious weed species.

Scientific Name	Common Name
Utah State—Listed Noxious Weeds	
Acroptilon repens	Russian knapweed
Cardaria spp.	Whitetop (all species)
Carduus nutans	Musk thistle
Centaurea diffusa	Diffuse knapweed
Centaurea solstitialis	Yellow star thistle
Centaurea stoebe ssp. micranthos	Spotted knapweed
Centaurea virgate ssp. Squarrosa	Squarrose knapweed
Cirsium arvense	Canada thistle
Convolvulus spp.	Bindweed (all species)
Cynodon dactylon	Bermuda grass
Elymus repens	Quackgrass
Euphorbia esula	Leafy spurge
Isatis tinctoria	Dyer's woad
Lepidium latifolium	Broadleaf pepperweed
Lythrum salicaria	Purple loosestrife
Onopordum acanthium	Scotch thistle
Sorghum almum	Perennial sorghum (all species)
Taeniatherum caput-medusae	Medusahead
San Juan County—Listed Noxious Weeds	
Aegilops cylindrical	Jointed goatgrass
Alhagi maurorum	Camelthorn
Asclepias subverticillata	Western whorled milkweed
Solanum elaeegnifolium	Silverleaf nightshade
Solanum rostratum	Buffalobur

Each survey will identify noxious weed populations and locate these populations on a map using a set of symbols to identify species, size of the infestation, and density of the population. The effectiveness of control methods will be documented in each annual survey. In addition, immediately adjacent off-site properties will be visually surveyed to a distance of 100 feet. Inspections will be conducted by personnel familiar with the identification of noxious weeds in the area and based on Utah's Noxious Weed List.

The selected control methods will be based on the type, size, and location of the mapped noxious weeds. The treated area(s) will be monitored and re-inspected annually for new weed introductions and to evaluate the success of the control methods. Prevention is the highest priority weed management practice on non-infested lands; therefore protecting weed-free plant communities is the most economical and efficient land management practice. Prevention is best accomplished by ensuring that new weed species seed or vegetative reproductive plant parts of weeds are not introduced into new areas, and by early detection of any new weed species before they begin to spread.

Control methods may include chemical or mechanical approaches. The optimum method or methods for weed management vary depending on a number of site-specific variables such as associated vegetation, weed type, stage of growth, and severity of the weed infestation.

Chemical Control

Chemical control consists mostly of selective and non-selective herbicides. Considerations for chemical controls include: herbicide selection, timing of application, target weed, desirable plant species being grown or that will be planted, number of applications per year and number of years a particular species will need to be treated for desired control. Also important are the health and safety factors involved, and the need to consider undesirable impacts. The use of herbicides will be in compliance with all Federal and State laws on proper use, storage, and disposal. The chemical application will be done by a licensed contractor in accordance with all applicable laws and regulations and all label instructions will be strictly followed. Applications of herbicides will not be permitted when the instructions on the herbicide label indicate conditions that are not optimal.

Mechanical Control

Mechanical control is the physical removal of weeds from the soil and includes tilling, mowing, and pulling undesirable plant species. Tillage is most effective prior to seeding and establishment of desirable vegetation. The tillage method of weed control can be effective in eliminating noxious perennial weeds when repeated at short intervals (every 1-2 weeks) throughout the growing season. Tillage has the drawback of indiscriminately impacting all vegetation interspersed with weeds in established areas and can eliminate competitive, desirable vegetation leaving behind a prime seedbed for weeds to reinvade. Mowing can be an effective method for controlling the spread of an infestation and preventing the formation and dispersal of seeds. Mowing is most effective on weeds which spread solely or primarily by seed. In order to achieve this, mowing must be repeated at least twice during the growing season prior to, or shortly after bloom. Also, even the most intense mowing treatment will not kill hardy perennial weeds. Additional considerations will be made when selecting control treatments when specific situations arise regarding type, size, and location of weed infestations. Examples of this are perennial versus biennial, broadleaf versus grasses, noxious weeds interspersed with desirable vegetation, large monoculture patches, or small patches requiring spot treatment.

Treatment windows schedules, based on the control methods chosen and the noxious weeds present, will be established for each treatment area. The best time to treat perennial noxious weeds is in the spring or fall during their active growth phase. Different species will have different optimum treatment times even with the same type of control. Perennial weeds usually grow vegetative in the spring, flower and seed in late spring and early summer, enter dormancy during the summer and actively grow again in the fall. The treatment windows selected will depend on the species present and control methods selected.

The final preparatory step is to determine the priority for areas to be treated. Prioritization ensures that the most important areas are dealt with at the most effective times. Important areas of concern include areas that may transport weed seeds. These areas include ditches, roadsides, and land equipment storage sites. Large monoculture patches are of concern wherever they occur and will always be high priority. Also, small patches of weeds will be treated to prevent expansion of weed populations.

Once the treatment plan is implemented, detailed records will be kept, and success or failure of treatment will be recorded so as to eliminate unsuccessful treatments.

9.8.4 Vegetation Establishment Performance

The following Revegetation Acceptance Goals/Criteria have been adapted from the Monticello Site and will be used at the Mill site to determine reclamation success.

Revegetation Acceptance Goal/Criteria:

Criterion 1 Species Composition

a. The vegetative cover (the percentage of ground surface covered by live plants) shall be composed of a minimum of five perennial grass species (at least four listed as native), one perennial forb species, and two shrub species listed in Table 9.1.

Criterion 2 Vegetative Cover

a. Attain a minimum vegetative cover percentage of 40 percent.
b. Individual grass and forb species listed in Table 9.1 that are used to achieve the cover criteria shall have a minimum relative cover (the cover of a plant species expressed as a percentage of total vegetative cover) of 4 percent and a maximum relative cover of 40 percent.
c. Individual species not listed in Table 9.1 may be accepted as part of the cover criteria if it is demonstrated that the species is native or adapted to the area and is a desirable component of the reclaimed project site.
d. Species not listed in Table 9.1, including annual weeds or other undesirable species such as those listed in Table 9.2, shall not count toward the minimum vegetative cover requirement. Every attempt shall be made to minimize establishment of all noxious weeds.

e. Reclaimed areas shall be free of state- and county-listed noxious weeds (Table 9.2).

f. The vegetative cover shall be self-regenerating and permanent. Self-regeneration shall be demonstrated by evidence of reproduction, such as tillers and seed production.

Criterion 3 Shrub Density

a. A minimum shrub density of 500 stems per acre.

b. Shrubs shall be healthy and have survived at least two complete growing seasons before being evaluated against success criteria.

Plant cover will be measured annually on the tailing cells for a minimum of ten years or until the revegetation goals stated above are achieved. Cover will be measured by the point method, using a vegetation sighting scope mounted on an adjustable tripod with a level. Cover will be measured for each species encountered, as well as litter, rock, and bareground. Cover measurements will be made along a minimum of ten randomly placed transects on each tailing cell that are 100 feet long. A total of 100 points will be sited at one-foot intervals along each transect to collect cover data in the categories of live vegetation, litter, rock, and bareground. Sample adequacy will be determined for each tailing cell using the following formula that identifies the minimum number of samples that are necessary to estimate the population mean at a 90 percent level of confidence. Total live vegetation cover will be used to calculate sample adequacy.

$$n = \frac{t^2 s^2}{(.10x)^2}$$

Where: n = minimum number of samples required to meet sample adequacy requirements

s^2 = variance

t^2 = 1.64 for 90% confidence

x = sample mean

Shrub density will be measured in belt transects placed on either side of the cover transects. All shrubs will be counted within a three-foot wide strip or belt transect along each side of the transect used for point cover measurements, resulting in a belt transect that is six-feet wide and 100 feet long.

In addition to the above cover sampling, annual observations will be made of overall plant community health and sustainability. Overall health will be based on plant vigor, presence of annual weeds, and signs of plant deficiencies or toxicities. Plant community sustainability will be based on observations of reproduction, including both vegetative reproduction, such as tillering, and seed production.

If revegetated areas are not making satisfactory progress in meeting revegetation goals outlined above, then remedial actions will be implemented as needed. These actions may include fertilization/soil amendments, reseeding, weed control, and/or erosion control depending upon the cause of the problem that may exist and the best remediation approach to ensure plant community success.

Exhibit A-1:
Daily QA/QC Checks

August 2016

1.0 INTRODUCTION

A background count rate and reliability check using a check source shall be performed daily, prior to use, when the detector/scaler is used for counting. Background count rates and source checks shall be input on a control chart after developing of the mean and standard deviation (sigma) as discussed below.

2.0 QC CONTROL CHARTING

Select a background location such as an office or other location where background gamma radiation gamma values are not expected to vary. Take ten 30-second count readings and record them on Form 1. Using the ten readings, calculate the mean, sigma, and 2 sigma). These results shall also be recorded on Form 1.

Daily, prior to use, and at the end of surveys, perform a 30-second background and source count at the same location and in the same configuration as the acceptable ranges were developed. If the background or source check result exceeds a difference of two standard deviations, (2s or 2 sigma) from the mean, as shown on Figure 2, the Instrument Control Chart, re-count the background or source, log the results, and enter the new data on the Instrument Control Chart. Two successive background or source check counts outside the 2s Instrument Control Chart range indicates possible problems with the detector/electronics.

Values between ± 2s of the mean net counts generally indicate normal operation of the instrument. Values outside the mean ± 2s will occur with a frequency of less than 5 percent. Values greater than 3s from the mean will occur with a frequency of less than one percent and should be investigated. Two consecutive measurements outside 3s indicate problems with equipment and require adjustments and/or repairs as necessary. The scaler shall be removed from service and immediate notification shall be made to the RSO or designee prior to counting any samples.

Calibrations shall be checked whenever a significant change or repair is made to the measurement system, or when changes are detected as a result of check source measurements.

Control charts shall be maintained to indicate instrument operability and/or malfunction problems on a daily basis when instruments are in use. Use the attached control chart. Control charts should be kept for both background counts and counts with a check source, such as a 5 µCi Cs-137 source.

FORM 1: CALCULATION OF INSTRUMENT STANDARD DEVIATION							
Date of 1st Instrument Use	Count 1	Count 2	Count 3	Count 4	Count 5	Count 6	Count 7
	Count 8	Count 9	Count 10	Sample Mean (λ)	Sample Standard Deviation (σ)	Lower Control Limit (λ-2s)	Upper Control Limit (λ+2s)

$$\lambda = \frac{1}{10}\sum_{i=1}^{10} n_i$$

Where λ is the mean of the counts, and n is the 30 second count rate

$$s = \sqrt{\frac{\sum_{i=1}^{m}(n_i - \lambda)}{9}}$$

Where σ is the standard deviation, λ is the mean of the counts, and n is the 30 second count rate

FORM 2: INSTRUMENT CONTROL CHART							
Initials	Date	Count	Sample Mean (λ)	Sample Standard Deviation (s)	Lower Control Limit (λ-2s)	Upper Control Limit (λ+2s)	Pass?

ATTACHMENT B

CONSTRUCTION QUALITY ASSURANCE/QUALITY CONTROL PLAN

FOR RECLAMATION OF WHITE MESA MILL FACILITY

BLANDING, UTAH

TABLE OF CONTENTS

1 INTRODUCTION

This Construction Quality Assurance/Quality Control Plan (CQA/QC Plan) has been prepared for construction activities related to the reclamation of the Energy Fuels Resources (USA) Inc. (”EFRI”) White Mesa Mill Facility located in Blanding, Utah and is submitted as an attachment to the Reclamation Plan.

1.1 Purpose and Scope

The purpose of this CQA/QC Plan is to address the Construction Quality Assurance (CQA) and Construction Quality Control (CQC) procedures and requirements to be used during reclamation activities at the site to assure that the project is constructed in conformance with the Technical Specifications, Drawings, and applicable regulatory requirements and permit conditions. The CQA/QC Plan is intended to: 1) define individuals and organizations who will be involved in reclamation activities and their respective responsibilities and qualifications; 2) establish guidelines for the flow of information and project communication; 3) establish protocols for project documentation; and 4) establish specific CQA/CQC procedures for the major components of the project.

This CQA/QC Plan addresses reclamation of the following facilities:

- Cell 1 (evaporation)
- Cells 2, 3, and 4A (tailings)
- Cell 4B (This cell is currently used for evaporation of process solutions. The CQA/QC Plan was written assuming this cell will be used for tailings storage in the future.)
- Mill buildings and equipment
- On-site contaminated areas
- Off-site contaminated areas (i.e., potential areas affected by windblown tailings)

The CQA/QC Plan has been written assuming tailings management Cells 2, 3, 4A, and 4B will receive tailings to the maximum permitted tailings elevations. Cell 2 is full and partially reclaimed. Cell 3 was used for tailings storage, but is currently only receiving mill waste. Cell 3 is partially full and partially reclaimed. Cell 4A is the only cell currently receiving tailings and is partially full. Cell 4B is used for evaporation of process solutions and has not yet been used for storage of tailings.

Reclamation of the above facilities will include the following:

- Placement of contaminated soils, crystals, and synthetic liner material and any contaminated underlying soils from Cell 1 into the last active tailings cell
- Placement of a compacted clay liner on a portion of the Cell 1 impoundment areas to be used for disposal of contaminated materials and debris from the Mill site
- Decommissioning the Cell 1 (evaporation) area
- Reclamation of the Mill and ancillary areas
- Placement of materials and debris from Mill decommissioning into the Cell 1 Disposal Area or the last active tailings cell
- Placement of an Evapotranspiration (ET) cover over the entire area of Cells 2, 3, 4A, 4B and the Cell 1 Disposal Area
- Construction of runoff control and diversion channels as necessary
- Reclamation of borrow sources

1.2 Definition of Terms

In the context of this CQA/QC Plan, the following definitions apply:

Construction Quality Assurance (CQA) – A planned and systematic pattern of means and actions designed to assure adequate confidence that the materials or services meet contractual and regulatory requirements and will perform satisfactorily in service. CQA refers to means and actions employed by the involved parties to assure conformity of the project work with this CQA/QC Plan, the Drawings, and the Technical Specifications.

Construction Quality Control (CQC) – Actions that provide a means to measure and regulate the characteristics of an item or service in relation to contractual and regulatory requirements. CQC refers to those actions taken by the Contractor, technicians, or other involved parties to verify that the materials and the workmanship meet the requirements of this CQA/QC Plan, the Drawings, and the Technical Specifications.

Technical Specifications – The document that prescribes requirements and standards for specific elements of the reclamation. This document is included as Attachment A to the Reclamation Plan. Technical Specifications will be prepared in final form prior to commencement of reclamation activities.

Drawings – Detailed project drawings to be used in conjunction with the Technical Specifications. These drawings will be prepared in final form as construction drawings prior to reclamation.

Construction Project – The total authorized/approved reclamation project that requires several construction segments to complete.

Construction Segment – A portion of the total construction project involving a specific area or type of work. Several construction segments will likely take place simultaneously during reclamation.

Construction Task – A basic construction feature of a construction segment involving a specific construction activity.

ASTM Standards – The latest versions of the American Society for Testing and Materials specifications, procedures and methods.

2 INVOLVED PARTIES AND PERSONNEL

Each construction task within each segment of the overall project will consist of both a QC and QA component. Compliance reporting will be completed for each segment. Upon completion of all project segments, a final construction report will be prepared for the project. Following is a listing of the parties (organizations and individuals) that will be involved in the implementation of the CQA/QC Plan during the reclamation at the site, including a discussion of each party's responsibility, authority and qualifications.

2.1 Owner

The Owner of this project is EFRI.

2.2 Construction Manager

Responsibility & Authority: The on-site Construction Manager is responsible for the conduct, direction and supervision of all reclamation activities as detailed in the Drawings and Technical Specifications. The Construction Manager will be selected/appointed by the Owner. The Construction Manager is responsible for maintaining a detailed schedule for the various Construction Segments so that each is performed according to the schedule for the overall Reclamation Project. The Construction Manager will interact as required with all other parties involved in implementing the reclamation including the Contractor, the CQA/QC personnel, and the DWMRC Project Manager. In the temporary absence of the Construction Manager, a designated representative will assume the duties of the Construction Manager. The Owner may appoint separate Construction Managers to oversee the various Construction Segments within the overall Reclamation Project. The Construction Manager(s) will report directly to the Owner.

Qualifications: The Construction Manager(s) shall have the mine and mill reclamation and construction experience necessary to manage a large-scale reclamation project.

2.3 Design Engineer

Responsibility & Authority: The Design Engineer is responsible for the design of the various elements of the reclamation project and for preparing the Drawings and Technical Specifications. Throughout the project, the Design Engineer will interact as necessary with the Owner, Construction Manager, CQA/QC staff, and the DWMRC Project Manager. The Design Engineer will approve all design changes that arise during the course of the Reclamation Project.

Qualifications: The Design Engineer shall be a qualified Professional Engineer registered in the State of Utah. The Design Engineer shall have expertise which demonstrates significant familiarity with the design and construction of the various elements of mine and Mill site reclamation including earthwork, cover design, mill demolition and disposal.

2.4 Contractor

Responsibility & Authority: The Contractor refers to an independent party or parties, contracted by the Owner, performing the work in accordance with this CQA/QC Plan, the Drawings, and the Technical Specifications. It is anticipated that various Contractors will be employed to perform the various Construction Segments within the overall Reclamation Project. The Contractor will work under the direction of and report directly to the Construction Manager.

Qualifications: Qualifications of the Contractor are specific to the construction contract and the specific Construction Segment. The Contractor shall have a demonstrated history of successful construction experience as appropriate for the Construction Segment. The Contractor shall maintain current state and federal licenses as appropriate.

2.5 Surveyor

Responsibility & Authority: The Surveyor is a party, independent from the Owner or Contractor, who is responsible for surveying, documenting, and verifying the location of all significant components of the work. The Surveyor is responsible for issuing Record Drawings of the completed elements of the Construction Project. The Surveyor's work is coordinated with the Contractor and CQA Consultant. The Surveyor will report directly to the Construction Manager.

Qualifications: The Surveyor will be a well-established surveying company with at least 3 years of surveying experience in the State of Utah. All survey activities shall be performed under the direction of a Professional Land Surveyor, licensed as required by State of Utah regulations. The Surveyor shall be fully equipped and experienced in the use of total stations and AutoCAD.

2.6 CQA/QC Consultant

Responsibility & Authority: The CQA/QC Consultant is a party, independent from the Owner or Contractor, who is responsible for observing, testing, and documenting the various activities comprising the Reclamation Project in accordance with this CQA/QC Plan, the Technical Specifications and the Drawings. The CQA/QC Consultant will be responsible for issuing a CQA report at the completion of the Reclamation Project which will document construction and associated CQA/QC activities. The CQA/QC Consultant will work in coordination with the Contractor, Surveyor and other parties and will report directly to the Construction Manager.

Qualifications: The CQA Consultant shall be a well-established firm specializing in geotechnical and reclamation engineering that possesses the equipment, personnel, and licenses necessary to conduct the observation and testing required. The CQA/QC Consultant will be experienced with earthwork, mill decommissioning, and other reclamation activities. The CQA/QC Consultant will be experienced in preparation of CQA documentation including field documentation, field testing procedures, laboratory testing procedures, and CQA reports.

The CQA Consultant will provide qualified staff for the project which will include the following individuals.

1) CQA Officer
2) CQA Site Manager
3) QC Technicians

2.7 CQA Officer

Responsibility & Authority: The CQA Officer will be responsible for overall implementation and management of the CQA/QC Plan for the reclamation project. The CQA Officer works from the office of the CQA Consultant and conducts periodic visits to the site as required. The CQA Officer will supervise the CQA Site Manager and all QC Technicians and will coordinate with the Surveyor, the Contractor and other staff. The CQA Officer will report directly to the Construction Manager.

The CQA Officer will be expected to maintain a thorough understanding of the existing White Mesa facilities and the reclamation project design documents including the Drawings, Technical

Specifications, and this CQA/QC Plan. He/she will have the authority to reject work or material, to require removal or placement, to specify and require appropriate corrective actions if it is determined that the Quality Control/Quality Assurance, personnel, instructions, controls, tests, or records are not conforming to the CQA/QC Plan, the Construction Plans, or the Technical Specifications. The approval of the CQA Officer is required on all Compliance Reports required in this CQA/QC Plan. Specific responsibilities of the CQA Officer will include the following:

1. Administer the CQA program (i.e., provide supervision of and manage all CQA personnel and activities)
2. Provide and document all necessary training and certifications for CQA personnel
3. Review and approve the Contractor's QC Plan(s), if applicable
4. Attend Project Kickoff and Pre-Construction Meetings, and make site visits as needed
5. Perform ongoing, timely review of all CQA documentation and provide signature on all CQA documentation

Qualifications: The CQA Officer will be a Professional Engineer registered in the State of Utah and will be experienced in providing CQA oversight for large construction projects.

2.8 CQA Site Manager

Responsibility & Authority: The CQA Site Manager will be appointed by the CQA Consultant to provide day-to-day, on-site oversight of the CQA/CQC activities. The CQA Site Manager will report directly to the CQA Officer and will interact with the Construction Manager, Contractor and others on a daily basis, as project activities take place. The CQA Site Manager will maintain a thorough understanding of the Drawings, Technical Specifications, and this CQA/QC Plan. Specific responsibilities of the CQA Site Manager will include the following:

1. Attend all CQA-related meetings including Project Kickoff and Pre-Construction Meetings
2. Provide direct oversight of QC Technicians
3. Assign locations for testing and sampling
4. Oversee the collection and shipping of laboratory test samples

5. Review results of field and laboratory testing and any test results provided by the Contractor and make appropriate recommendations
6. Review the calibration and condition of onsite testing equipment, and maintain necessary equipment documentation
7. Report any deviations from the CQA/QC Plan, Drawings, or Technical Specifications to the Construction Manager and CQA Officer and arrange consultation with other parties as necessary to find solutions to unsolved problems
8. Prepare a daily field report for submittal to the CQA Officer and Construction Manager

Qualifications: The CQA Site Manager will be an engineer experienced in providing field CQA/CQC oversight for construction projects.

2.9 QC Technicians

Responsibility & Authority: The CQA Consultant will utilize various QC Technicians to assist the on-site CQA Site Manager to perform specific tasks through the project to verify the adequacy of construction materials and procedures. The QC Technicians will work under the direct supervision of the CQA Site Manger and will work in close coordination with the Contractor. The number of technicians will depend on the project needs as the work progresses.

Qualifications: The CQA Consultant will identify areas of competency and select technicians as necessary. The QC Technicians will receive on-the-job training or off-site training as required under the direction of the CQA Consultant. The CQA Officer will determine the areas of expertise of the respective technician and maintain a file on each technician's training and certifications.

2.10 Document Control Officer

Responsibility & Authority: The Document Control Officer will be appointed by the Construction Manager to assist with managing the various documents that will be produced throughout the project. The Document Control Officer will maintain permanent files for the Construction Project. All tests, surveys, monitoring and report originals will be maintained in the project files. The Document Control Officer will oversee document reproduction and distribution. A distribution list will be prepared in coordination with the Owner, Construction Manager, and CQA Officer.

Qualifications: The Document Control Officer will have the organizational and computer skills necessary to manage and distribute the various project documents.

2.11 CQA Laboratory

Responsibility & Authority: The CQA Laboratory is a party, independent from the Owner and Contractor, responsible for conducting tests of soils and other project materials in accordance with ASTM and other applicable standards in either an on-site or off-site laboratory. It is likely that more than one CQA Laboratory will be used to perform testing during reclamation activities, depending upon the material being tested. The CQA Laboratory will work in coordination with other personnel and will report directly to the CQA Consultant.

Qualifications: The CQA Laboratory will be an AASHTO AMRL accredited laboratory in testing soils using the ASTM standards outlined in the Technical Specifications. The CQA Laboratory will be capable of providing test results within a maximum of seven days of receipt of samples and will maintain that capability throughout the duration of the project.

2.12 DWMRC Project Manager

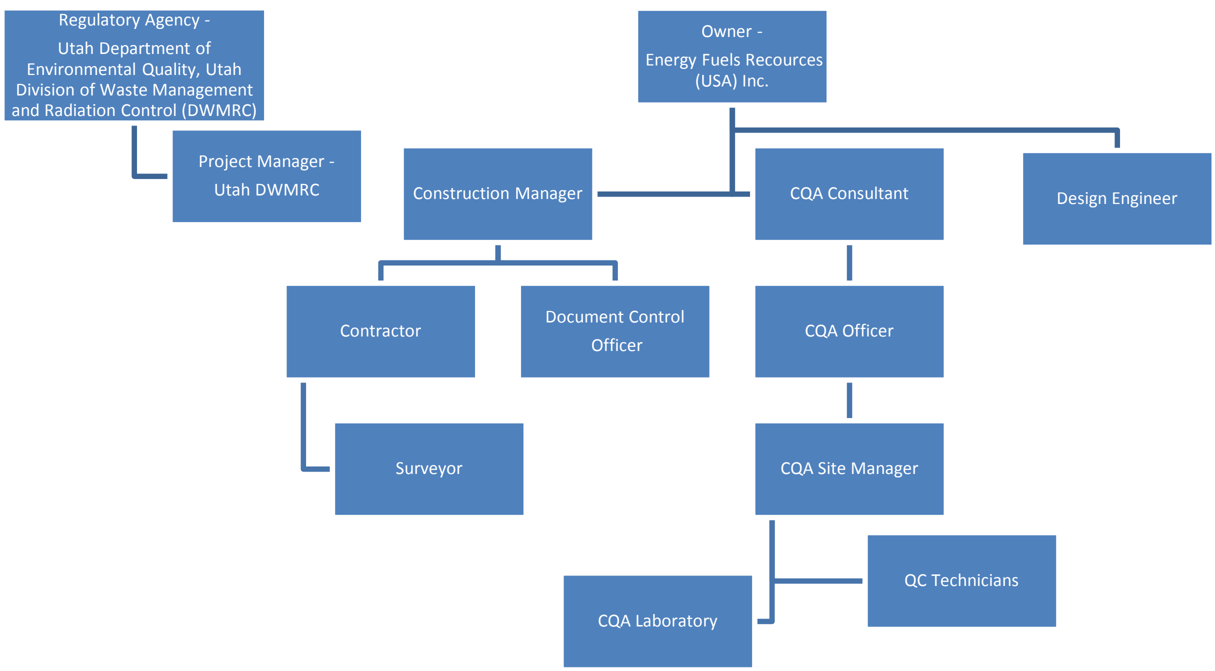
The DWMRC Project Manager will represent the DWMRC's interests in the Reclamation Project. The DWMRC Project Manager may choose to review selected procedures, personnel qualifications, equipment, calculations, and documentation. DWMRC personnel will be granted full access to the project files upon request.

3 PROJECT COMMUNICATION

3.1 Flow of Information

Effective communication is necessary to ensure a high degree of quality during the Reclamation Project. Specific meetings of key project personnel will take place including a Project Kickoff Meeting, Pre-Construction Meetings, weekly Progress Meetings, and Problem or Work Deficiency Meetings. In addition, informal communication and cooperation will take place between the various parties listed in Section 2 above. The organizational chart showing the proposed lines of communication between the various parties is shown in Figure 1. The planned project meetings are described in the following sections.

Figure 1 – Project Organization



3.2 Project Kickoff Meeting

At the beginning of major reclamation activities, a Project Kickoff Meeting will take place at the site. At a minimum, this meeting will be attended by the Owner, the Construction Manager, the Contractors, the CQA Consultant, the Engineer, and the DWMRC Project Manager. The Construction Manager will conduct a site tour to observe the current site conditions and to identify various areas of the site including equipment storage areas, soil stockpiling areas, and staging areas. The Construction Manager will appoint an individual to record the discussions and decisions of the meeting and distribute meeting minutes to all attendees. Specific items for discussion will include:

1. The Drawings, Technical Specifications, and CQA/QC Plan and any modifications or clarifications to these documents
2. Lines of communication and authority
3. The responsibilities of each party
4. The overall schedule for the Reclamation Project and the anticipated sequencing and schedule of the various Construction Segments
5. Documentation requirements

3.3 Pre-Construction Meetings

The overall Reclamation Project will be comprised of several individual Construction Segments. At the beginning of each Construction Segment, a Pre-Construction meeting will take place at the site and will be attended by the Construction Manager, the Contractor, the CQA Consultant, and the DWMRC Project Manager. The Construction Manager will conduct a tour of the work area to observe the current site conditions and to identify various areas of the site including equipment storage areas, soil stockpiling areas, staging areas, and other details related to the Construction Segment. The Construction Manager will appoint an individual to record the discussions and decisions of the meeting and distribute meeting minutes to all attendees. Specific items for discussion at the Pre-Construction Meetings include the following:

1. The Drawings, Technical Specifications, and CQA/QC Plan and any modifications or clarifications to these documents

2. Safety procedures
3. Lines of communication and authority
4. The responsibilities of each party
5. The overall schedule for the Construction Segment
6. Acceptance and rejection criteria
7. Protocols for handling deficiencies, repairs, and re-testing
8. Documentation requirements

3.4 Progress Meetings

Progress meetings will be held weekly between the CQA Site Manager, the Contractor, the Construction Manager, and other concerned parties participating in the construction of the project. This meeting will include discussions of the progress of the project, planned activities for the next week, and revisions to the work plan or schedule. The Construction Manager will appoint an individual to document the meeting and send meeting minutes to all attendees for review and comment.

3.5 Problem or Work Deficiency Meetings

It is anticipated that most work deficiencies will be minor and can be resolved in the field by the QC Technicians, the CQA Site Manager, and the Contractor. The deficiency and resolution will be recorded in daily field reports and weekly summary reports prepared by the CQA Site Manager.

A special meeting will be held when a problem or deficiency is present, or likely to occur, that cannot be easily resolved in the field. The meeting will be attended by the Contractor, the Construction Manager, the CQA Site Manager, and other parties as appropriate. If the problem requires a design modification, the Engineer should either be present at, consulted prior to, or notified immediately upon conclusion of this meeting. The Construction Manager will appoint an individual to record the meeting and send meeting minutes to all attendees for review and approval. The purpose of the work deficiency meeting is to define and resolve the problem or work deficiency as follows:

1. Define and discuss the problem or deficiency
2. Review alternative solutions
3. Select a suitable solution agreeable to all parties
4. Implement an action plan to resolve the problem or deficiency

4 DOCUMENTATION

4.1 Overview

The CQA Consultant will be responsible to prepare documentation that demonstrates that CQA/CQC requirements have been addressed and satisfied. Documentation will include monitoring logs, testing data sheets, photo logs, equipment calibration forms, daily field reports, weekly summary reports, reports of design or specification changes, and a final CQA Report. Documentation will be maintained in the White Mesa Project files and will be available to the Owner, Engineer, CQA Officer, and the DWMRC Project Manager at all times.

The CQA Officer and Site Manager will be responsible for preparing forms required throughout the Reclamation Project. These forms will be used by QC Technicians and other parties to document QC activities.

4.2 Daily Field Reports

The CQA Site Manager will prepare daily field reports that will document each day's activities. These daily reports will include the following, as applicable:

1. Basic information including date, project name, weather conditions, and the applicable Construction Segment
2. A summary of construction locations, activities, and observations an QC activities performed
3. Equipment and personnel on the project and a summary of meetings and attendees
4. Monitoring logs, testing data sheets, photo logs, and equipment calibration forms
5. A description of materials used and result of testing and documentation
6. Laboratory test reports
7. Reports of construction problems and resolution data sheets
8. Identification of deficient work or materials, and results of re-testing of deficient work
9. The signature of the CQA Site Manager

4.3 Weekly Summary Reports

At the end of each work week, a weekly summary report will be prepared and submitted to the Construction Manager and the CQA Officer. Weekly summary reports will include a brief description of the week's activities and all of the week's daily field reports. The CQA Officer will be responsible to review and sign each weekly summary report.

4.4 Field Change Reports

Changes that do not alter the intent of the Construction Plans or Technical Specifications may be made during construction to fit field conditions. Field changes require the approval of the Construction Manager and the CQA Site Manager. Field changes are to be reported on Form No. F-25 (Included in Section 6.0).

4.5 Construction Problems and Resolution Data Sheets

If significant recurring nonconformance occurs, or if special construction situations arise, the Construction Manager and CQA Officer will be made aware of the situation. The cause of the nonconformance will be determined and appropriate changes in procedures or specifications may be recommended. A Construction Problems and Resolution Data Sheet will be prepared to describe the situation and the resolution. Supporting documentation, such as photos or testing data sheets, will be attached to the data sheet. Data sheets will be included in the daily field reports and weekly summary reports.

4.6 Design or Specification Changes

During construction, design or specification changes may be required. Design changes will require the written approval of the Engineer and will take the form of technical memorandum and/or an addendum to the Drawings or Technical Specifications. Design changes are to be reported on Form No. F-26 (Included in Section 6.0).

4.7 CQA Compliance Reports

At the completion of each Construction Segment, the CQA Consultant will prepare a CQA Compliance Report signed and sealed by a Professional Engineer licensed in the State of Utah. The CQA Report will acknowledge that the work has been performed in conformance with the

Drawings and Technical Specifications. The CQA Report will incorporate supporting documentation including:

1. All daily field reports and weekly summary reports
2. Laboratory test reports
3. Field change reports
4. Construction problems and resolution data sheets
5. Documentation of design or specification changes

Any subsequent Construction Segment that is dependent upon successful completion of a specific Construction Segment cannot be initiated until a Compliance Report is prepared and approved for the previous dependent Construction Segment. Compliance Reports are to be completed on Form No. F-23 (Included in Section 6.0).

4.8 Final Construction Report

At the conclusion of the Reclamation Project, the Construction Manager or a designated representative will prepare a Final Construction Report. This report will be submitted to the DWMRC for review and approval within 180 calendar days after completion of construction. This report will be prepared under the direct supervision of and stamped by a Professional Engineer registered in the state of Utah. This report will include, at a minimum:

1. All of the individual CQA Compliance Reports which will summarize all CQA/CQC operations, construction equipment and processes, results, and observations of conformance/verification testing
2. A summary of any actions taken to resolve construction problems encountered
3. Field notes and photographs
4. As-built drawings and details

5 CQA/CQC PROCEDURES

This section describes the CQA/CQC monitoring and testing procedures to be used during the Reclamation Project to ensure that construction takes place in accordance with the Drawings and Technical Specifications. Specific requirements for construction procedures and materials are presented in the Drawings and Technical Specifications, along with criteria for site cleanup activities. If there is a conflict between CQA/QC procedures presented herein and those presented in the Technical Specifications, those presented in the Technical Specifications shall take precedence unless otherwise indicated by the Design Engineer.

5.1 Contractor Evaluation

Prior to construction, each Contractor will submit a summary of proposed construction methods, equipment and testing protocols. The Construction Manager, CQA Officer, and Engineer will review the submittal and provide approval, in writing, of the Contractor's plans. The Contractor may be required to modify proposed methods, equipment, or testing protocols prior to approval.

5.2 Testing Methods

Throughout the Reclamation Project, various field and laboratory testing will be conducted to ensure that materials meet the Technical Specifications. Where applicable, testing will be conducted in accordance with the current versions of the corresponding ASTM test procedures. Any revisions to the testing methods will be reviewed and approved by the Engineer and the CQA Officer prior to usage. Testing methods to be used are summarized in Table 1. The required frequency of testing is described in the applicable Sections that follow.

Table 1 - Summary of Testing Methods

TEST METHOD	TEST STANDARD
Particle Size Analysis (Gradation)	ASTM D422
Atterberg Limits	ASTM D4318
Standard Proctor	ASTM D698
Rock Correction of Unit Weight & Water Content	ASTM D4718
Nuclear Moisture/Density Gauge	ASTM D6938

TEST METHOD	TEST STANDARD
Sand-Cone Test	ASTM D1556
Moisture Content	ASTM D2216
LA Abrasion – Coarse	ASTM C535
LA Abrasion – Fine	ASTM C131
Specific Gravity – Aggregate	ASTM C127
Absorption – Aggregate	ASTM C127
Sodium Soundness – Aggregate	ASTM C88

During earthwork operations and fill placement, testing will be conducted to verify that the materials meet the gradation and classification specifications. Testing will include gradation testing (ASTM D422) and Atterberg Limit testing (ASTM D4318).

Moisture-density curves will be developed using the standard Proctor test (ASTM D698). Rock corrections (ASTM D4718) for the Proctor tests may be required depending on the material being tested. Field density testing may be conducted with the sand cone test (ASTM D1556) or a nuclear density gauge (ASTM D6938, or as modified by the QA Manager). Correlation of nuclear density gauge results shall be by comparison with results from sand cone test(s) and laboratory testing for water content(s) using the oven drying method (ASTM D2216) on similar material. A sufficient number of sand cone tests and moisture content tests will be performed to provide a correlation between the sand cone and nuclear density tests.

Rock protection aggregate will be tested using the LA Abrasion test for coarse or fine material (ASTM C535 or C131), the sodium soundness test (ASTM C88), and the specific gravity and absorption test (ASTM C127).

Other field or laboratory testing may be required throughout the Reclamation Project. Any testing shall be performed in accordance with the applicable ASTM or other industry standard.

5.3 Cell 1 Reclamation

Reclamation of Cell 1 will include the removal of contaminated materials including raffinate crystals, PVC liner, and contaminated site soils and the construction of a clay-lined area for permanent disposal of contaminated site materials. This disposal area (the Cell 1 Disposal Area) will be constructed adjacent to and parallel with the existing Cell 1 dike. A sedimentation basin will then be constructed and a drainage channel provided.

5.3.1 Removal of Contaminated Materials

QC staff will monitor of the removal of raffinate crystals, liner, and contaminated soils from Cell 1 and placement in the designated area. QC procedures for the placement of these materials are described in Section 5.4.

5.3.2 Subgrade Preparation

Subgrade for the clay liner may be leveled and filled as needed to provide a stable base for the placement of the clay liner. The QC staff will monitor placement and compaction of any subgrade fill.

5.3.3 Clay-Lined Cell 1 Disposal Area

A clay lined area will be constructed adjacent to and parallel with the existing Cell 1 dike for permanent disposal of contaminated material and debris. Tailings will not be placed in the Cell 1 Disposal Area. The area will be lined with a 12-inch thick clay layer prior to placement of contaminated materials and installation of the final reclamation cap. Placement of clay liner materials will be based on a schedule determined by the availability of contaminated materials removed from the Mill decommissioning area in order to maintain optimum moisture content of the clay liner prior to placing of contaminated materials.

5.3.4 Clay Liner Material Conformance Monitoring and Testing

The CQA Contractor will perform monitoring and frequent verification testing to verify that the clay liner material meets the gradation and classification specifications. The CQA Contractor will monitor earthmoving operations to ensure that fill material is taken from the proper borrow sources.

Clay liner material shall have a D_{100} particle size of less than 1-inch (100 percent passing the 1-inch sieve), and shall be free from roots, branches, rubbish, and process area debris. Liner material shall have a minimum of 40 percent passing the No. 200 sieve and a minimum plasticity index (PI) of 15. Suitable soils will classify as CL, CH, or SC materials under the Unified Soil Classification System.

Gradation and Atterberg limits testing will be performed at a minimum of one test per 2,000 cubic yards of clay liner material placed or when the material shows significant variation. Samples should be randomly selected for testing.

Laboratory test results for the clay liner shall be verified for compliance and approved by the CQA site manager prior to placement of disposed materials in the cell.

5.3.5 Clay Liner and Subgrade Material Placement

QC Technicians will observe the surface condition prior to fill placement. If the compacted surface of any layer of fill is too dry or smooth to bond properly with the layer of material to be placed thereon, it will be moistened and/or reworked with a harrow, scarifier, or other suitable equipment to a sufficient depth to provide relatively uniform moisture content and a satisfactory bonding surface before the next succeeding layer of fill is placed. If the compacted surface of any layer of fill is too wet (due to precipitation) for proper compaction, it will be reworked with harrow, scarifier or other suitable equipment to dry out the layer and reduce the moisture content to within the required limits. It will then be recompacted to the specified requirements.

QC Technicians will monitor the weather and temperature conditions. No material will be placed when fill material or the underlying material is frozen or when ambient temperatures do not permit the placement or compaction of the materials to the specified density without developing frost lenses in the fill.

The QC Technicians will monitor lift thicknesses frequently to verify the Technical Specifications are being met. The required layer and lift thicknesses for the clay liner and subgrade fill are listed in Table 2.

Table 2 - Summary of Liner Component Layers and Lift Thicknesses

Liner Component	Material Type (USCS)	Layer Thickness	Lift Thickness
Subgrade Fill	CL, ML, SC, SP, or SM	Variable	8 in. loose (max.)
Clay Liner	CL, SC, or CH	12 in. (min.)	6 in. loose (max.)

5.3.6 Moisture and Density Control

The QC Technicians will monitor placement, moisture conditioning, and compaction of the fill as it is placed. Prior to the start of field compaction operations, appropriate laboratory compaction curves will be obtained for the range of materials to be placed. Laboratory compaction curves based on complete Proctor tests will be obtained at the frequencies outlined in Table 3, depending on the variability of materials being placed.

Each layer of the fill will be conditioned so that the moisture content is uniform throughout the layer prior to and during compaction. As far as practicable, materials will be brought to the proper moisture content before placement. If necessary, water will be added after lift placement to the material by sprinkling on the layer. Each lift will be compacted by a sufficient number of roller passes or other compaction equipment to achieve the required dry density. Material that is too dry or too wet or does not meet the required dry density will be rejected and reworked until the moisture content and dry density are within the specified limits. Reworking may include removal, re-harrowing, reconditioning, rerolling, or combinations of these procedures.

The required density testing frequencies are included in Table 3. For all materials, a minimum of two tests will be taken for each day that more than 150 cubic yards of material is placed. A minimum of one test per lift and at least one test for every full shift of compaction operations will be taken.

Field density testing may be conducted with the sand cone test (ASTM D1556) or a nuclear density gauge (ASTM D6938, or as modified by the QA Manager). Correlation of nuclear density gauge results shall be by comparison with results from sand cone test(s) and laboratory testing for water content(s) using the oven drying method (ASTM D2216) on similar material. A sufficient number of sand cone tests and moisture content tests will be performed to provide a correlation between the sand cone and nuclear density tests. Field density tests shall be compared with standard Proctor tests (ASTM D698 Method A or C) on the same material.

Testing frequency may be increased by the CQA Site Manager if variability of materials is noted at the site, during adverse conditions, or to isolate failing areas of the construction.

Field density testing should not jeopardize the integrity of the clay liner. Holes in the clay material resulting from testing should be repaired by hand by filling with clay fill, or by filling with bentonite powder which is hydrated to fully seal the hole.

Table 3 - Summary of Liner Component Moisture-Density Testing Frequencies and Requirements

Liner Component	Test Frequency	Density Requirement*	Moisture Requirement*	Proctor Frequency
Subgrade Fill	1/1,000 cubic yards placed	90% (min.)	+/- 3%	1/10,000cubic yards placed
Clay Liner	1/500 cubic yards placed	95% (min.)	+/- 2%	1/5,000 cubic yards placed

* Based on maximum dry density and optimum water contents as determined by standard Proctor tests (ASTM D698 Method A or C) on the same material.

5.3.7 Sedimentation Basin and Discharge Channel

After contaminated material is removed from Cell 1 and the Cell 1 Disposal Area clay liner has been constructed, Cell 1 will be breached and constructed as a sedimentation basin. A discharge channel out of the sedimentation basin will be constructed. Details of these features are provided in the Drawings and Technical Specifications. The QC staff will monitor the excavation and construction of these features to ensure conformance with the Technical Specifications.

The channel excavation will be located within competent bedrock. The CQA team must document and verify the competency of the sedimentary bedrock along the channel for the Engineer and the Owner’s approval.

5.3.8 Riprap Conformance Monitoring and Testing

A rock apron will be constructed at the transition from soil to bedrock within the sedimentation basin. Rock apron riprap material of the specified size shall have a minimum rock quality designation or durability score of 70 or higher. If actual rock quality designation is between 65 and 69, oversizing will be required. Rock quality designations below 65 will not be acceptable.

The rock size specifications for the riprap shall be confirmed by particle-size distribution testing prior to placement, using ASTM D422, ASTM D5519, or an approved equivalent method for large-sized material. Testing shall be at a frequency of at least one test per 10,000 cubic yards of riprap placed, per select size, or when riprap characteristics show significant variation.

Test series for rock durability will include specific gravity, absorption, sodium soundness and LA abrasion. During construction additional test series and gradations will be performed for each type of riprap when approximately one-third (1/3) and two-thirds (2/3) of the total volume of each type have been produced or delivered. For any type of rock where the volume is greater than 30,000 cubic yards, a test series and gradations will be performed for each additional 10,000 cubic yards of rock produced or delivered.

5.3.9 Riprap and Filter Material Placement

In subgrade areas requiring fill placement to achieve final grades, after liner removal, the upper 12 inches shall be scarified, moisture conditioned and compacted prior to fill placement.

Filter material and riprap shall be placed in one or more lifts to form a continuous, uniform layer on top with a minimum thickness as identified in the Drawings. The top surface of the riprap shall be track-rolled or tamped with the bucket of a track-hoe to provide a uniform riprap surface and minimize void spaces within the riprap.

5.3.10 Tolerances

Completed grading for the sedimentation basin, in soil, shall be within 1.0 foot (horizontally) of the lines as designed, and within 0.1 foot (vertically) of the elevations as designed. Final surfaces shall be smoothed to avoid abrupt changes in surface grade or areas of runoff concentration.

The completed grading for the discharge channel (and portions of the sedimentation basin) in rock shall be within 2.0 foot (horizontally) of the lines as designed, and within 0.5 foot (vertically) of the elevations as designed. The final rock surfaces will be rough and shall not be filled to make grade. The bedrock channel shall be constructed at or below the design grades in order to meet the intent of the design.

5.3.11 Nonconformance, Corrective Action and Stop Work

The CQA staff, including the CQA Site Manager and QC Technicians, will have the authority to reject material brought to the site or material that has been placed. For a failed field moisture/density test, the QC Technician will determine the extent and depth of the affected area and require the Contractor to re-work the material as described above. If persistent failed tests occur (indicating inadequate compaction methods), the CQA Site Manager will have the authority to stop the work until the underlying cause is determined and the Contractor can demonstrate that moisture/density specifications can be met.

Laboratory test results for the clay liner shall be verified for compliance and approved by the CQA site manager prior to placement of disposed materials in the cell.

5.3.12 Documentation

Field and laboratory test results, observations of fill placement, and field compaction test results will be recorded using the appropriate field forms and reports, as described in Section 4. Table 4 includes a summary of the required materials testing and frequencies.

Table 4 - Summary of Testing Frequency and Criteria for Clay Liner and Sedimentation Basin Riprap

Component	Test	ASTM Standard	Frequency	Criteria
Clay Liner	Gradation (200 Wash)	D422	1/2,000cubic yards	40% min. passing the 200 sieve
	Atterberg Limits	D4318	1/2,000 cubic yards	Min. PI = 15
Riprap*	Gradation with 200 Wash	D422	1/10,000 cubic yards	D_{50}, Durability

*Rock durability testing per section 5.3.8

5.4 Mill Decommissioning

Decommissioning of the Mill will include:

- Disposal of the Mill processing equipment and structures and contaminated soils in the Mill area
- Cleanup of contaminated areas of the Mill Site including ore storage area and roadways
- Cleanup of windblown contamination

These areas are shown on the Drawings. The Technical Specifications describe methods and cleanup criteria, including radiological equipment that will be used and the development of cleanup criteria. Contaminated materials will be disposed of in the designated areas of the tailings impoundment.

The CQA Contractor will provide specialized QC Technicians qualified to monitor the dismantling of the Mill equipment and structures and the cleanup of contaminated soils. These Technicians will be trained in the proper use and calibration of radiological monitoring equipment and will monitor the work to ensure the cleanup criteria are met.

5.4.1 Characterization Surveys

Following scanning, classification and cleanup (as required), the areas will be scanned again to verify compliance with activity criteria. QC Technicians will use calibrated beta/gamma instruments capable of detecting activity levels of less than or equal to 25 percent of the guideline values.

After removal of contamination, the technicians will make final surveys over the remediated areas. The QC Technicians will document within the specific ten meter by ten meter grids, the sample point locations, as detailed in the Technical Specifications. Soil samples from 10 percent of the surveyed grids will be chemically analyzed to confirm the initial correlation factors utilized and confirm the success of cleanup effort for radium, thorium and uranium. Ten percent of the samples chemically analyzed will be split and duplicates will be sent to an off-site laboratory. Spikes and blanks, equal to 10 percent of the samples that are chemically analyzed, will be processed with the samples.

5.4.2 Contaminated Material Disposal

Contaminated materials including mill debris, site soils, liner material, and raffinate crystals will be disposed of in the designated portion of the Cell 1 Disposal Area. Material specifications and placement methods are described in the Construction Plans and Technical Specifications. The CQA Contractor will provide monitoring and testing during material placement.

5.4.3 Material Conformance Monitoring

For scrap and debris, the QC Technicians will monitor the volume and size of the material to ensure compliance with the maximum dimensions provided in the Technical Specifications (a maximum dimension of 20 feet and a maximum volume of 30 cubic ft) and to ensure that containers are properly pierced. If the size limits are exceeded, the QC staff will require the Contractor cut the material down to size.

5.4.4 Material Placement

QC Technicians will monitor material placement to verify the debris is spread out and placed according to the Technical Specifications and that voids are filled with stockpiled soils, contaminated soils, tailings and/or other approved materials. The approval of the Construction Manager and CQA Officer will be required for the use of other materials to fill voids.

A minimum of one foot of compacted soil will be required above the clay liner prior to placing any scrap or debris.

When liner or other lightweight material is placed, the QC staff will ensure that at least one foot of soil, crystals or other materials is placed above for protection against wind.

To the extent practicable, the various materials will not be concentrated in thick deposits on top of the tailings, but will be spread over the working surface as much as possible to provide relatively uniform settlement and consolidation characteristics of the cleanup materials.

It is anticipated that raffinate crystals will have a consistency similar to a granular material when brought to the cells, with large crystal masses being broken down for transport. Placement of the crystals will be performed as a granular fill, with care being taken to avoid nesting of large sized material. Actual placement procedures will be evaluated by the QC staff during construction as crystal materials are brought and placed in the cells.

Soil or soil-like material shall be placed and compacted over each lift of debris or other materials in lifts not to exceed two feet in loose thickness and compacted prior to placement of additional lifts.

5.4.5 Material Compaction

CQA staff will monitor material compaction to verify compliance with the Technical Specifications. The first lift (bridging lift) will be compacted by the tracking of heavy equipment, such as a Caterpillar D6 Dozer (or equivalent), using at least 4 passes, prior to the placement of a subsequent lift. Contaminated soils and other cleanup materials after the bridging lift will be compacted to the density requirement provided in the Technical Specifications. During construction, compaction requirements for the raffinate crystals will be re-evaluated based on field conditions and modified by the Construction Manager and CQA Officer, with the agreement of the DWMRC personnel.

Soil or similar material shall be compacted with a minimum of six passes with self-propelled, towed, or hand-held vibratory compaction equipment. The number of passes shall be confirmed with actual compaction equipment on site with a field test section of soil to establish a correlation between the field compaction method and 80 percent of maximum dry density for the soil, as determined by the standard Proctor test (ASTM D698).

The upper 12 inches of the final disposed material surface shall be compacted to 90 percent of the maximum dry density for the material, as determined by the standard Proctor test.

Field density tests shall be compared with standard Proctor tests (ASTM D698 Method A or C) on the same material. Standard Proctor tests shall be conducted at a frequency of at least one test

per 5,000 cubic yards of material compacted, or when material characteristics show significant variation.

Field density testing may be conducted with the sand cone test (ASTM D1556) or a nuclear density gauge (ASTM D6938, or as modified by the QA Manager). Correlation of nuclear density gauge results shall be by comparison with results from sand cone test(s) and laboratory testing for water content(s) using the oven drying method (ASTM D2216) on similar material. A sufficient number of sand cone tests and moisture content tests will be performed to provide a correlation between the sand cone and nuclear density tests.

The frequency of the field density and moisture tests will be not less than one test per 1,000 cubic yards of compacted fill. A minimum of two tests will be taken for each day that more than 150 cubic yards of material is placed. A minimum of one test per lift and at least one test for every full shift of compaction operations will be taken. Tables 5 and 6 summarize the placement and testing criteria for the disposed materials.

Table 5 - Summary of Disposed Materials and Lift Thicknesses

Disposed Materials	Material Type (USCS)	Layer Thickness	Lift Thickness
Debris Lift	Variable	48 in. (max.)	As needed to fill voids
Fill Above Debris Lift	Variable	36 in. (min.)	12 in. compacted (max.)

Table 6 - Summary of Disposed Materials Moisture-Density Testing Frequencies and Requirements

Disposed Materials	Test Frequency	Density Requirement *	Proctor Frequency
Fill around debris	1/1,000 cubic yards placed	80% (min.)	1/5,000 cubic yards placed
Upper Debris Fill	1/1,000 cubic yards placed	90% (min.)	1/5,000 cubic yards placed

* Based on maximum dry density and optimum water contents as determined by standard Proctor tests (ASTM D698 Method A or C) on the same material.

5.4.6 Final Slope and Grades

The final disposed material surface shall have maximum side slopes of 5:1 and a top surface sloping in the directions and grades shown on the Drawings. The side slopes and top surface shall be free from abrupt changes in grade or areas of runoff concentration. The final disposed material surface shall be compacted with approved construction equipment to form a smooth surface with uniform density for subsequent cover placement.

5.4.7 Tolerances

The final surface of the disposed material shall be smoothed to avoid abrupt changes in surface grade. The layer thicknesses shall meet the required minimum thicknesses.

5.4.8 Nonconformance, Corrective Action and Stop Work

The CQA Site Manager and QC Technicians will have the authority to reject scrap and debris that is not properly prepared for placement. The Contractor may be required to reduce the size of large pieces of material or pierce drums or other containers. CQ staff may also require site soils to be re-worked if a failed test indicates the compaction requirements were not met. If persistent inadequacies occur during the placement of contaminated materials, the CQA Site Manager will have the authority to stop the work until the underlying cause is determined and the Contractor can demonstrate that the Technical Specifications can be met.

5.4.9 Documentation

All observations and monitoring of contaminated material placement and all field compaction test results will be recorded using the appropriate field forms and reports, as described in Section 4.

5.5 Settlement Plates

The CQA team will need to verify proper construction and placement of the settlement points. The Surveyor will conduct the settlement plate measurements based on the DWMRC approved monitoring plan.

5.6 Cover System

A multi-layered earthen cover will be placed over tailings Cells 2, 3, 4A, and 4B and the portion of Cell 1 used for disposal of contaminated materials (the Cell 1 Disposal Area). The cover layers, from bottom to top, will include: 1) interim fill layer, 2) compacted cover layer 3) growth medium layer, and 4) erosion protection layer. Layers 1 through 3 will consist of “random fill.”

The material specifications, layer configurations, layer thicknesses, borrow sources, placement methods, and compaction requirements are described in the Technical Specifications. The CQA Contractor will provide monitoring and testing during material placement.

5.6.1 Material Conformance Monitoring and Testing

The CQA Contractor will perform monitoring and frequent verification testing to ensure that the fill materials meet the gradation and classifications specifications. The CQA Consultant will monitor earthmoving operations to ensure that the fill material is taken from the proper borrow sources.

Prior to the placement of the next layer of the cover, the CQA Site Manager or the QC Technicians under the supervision of the CQA Site Manager shall inspect the completed layer and document any of the following:

- Erosion of the layer surface
- Cracking or desiccation of the surface
- Fill areas that may contain excessive organics or other debris
- Depressions, or settlement of the layer
- Irregularities in the layer surface (e.g. grading errors)

Any documented items that constitute non-conformance with the Drawings and Technical Specifications should be corrected prior to placement of the subsequent layer of the cover.

5.6.1.1 Random Fill

Random fill will be used for each of the lower three layers of the cover system. The fill will consist of mixtures of sands and silts with varying amounts of clay and random amounts of gravel and rock-size material. Random fill, except for the interim fill layer, shall have a maximum particle size of 6 inches, and at least 10 percent of the material shall be finer than the No. 200 sieve. Oversized material will be controlled through selective excavation at the stockpiles and through the utilization of a grader, bulldozer or backhoe to cull oversize materials from the fill. The source of these materials will be site stockpiles from previous cell construction activities.

Testing for all layers except the interim fill shall consist of No. 200 sieve wash and particle-size distribution testing (ASTM D422) at a frequency of at least one test per 2,000 cubic yards of fill placed, or when material characteristics show a significant variation.

5.6.1.2 Topsoil-Gravel Admixture

Topsoil-gravel admixture material shall be free from roots, branches, rubbish, and debris. The gravel portion of the topsoil-gravel admixture material will consist of granular materials from approved off-site sources.

The mixture will be 25 percent gravel by weight. The gravel will be purchased from nearby commercial sources of alluvial gravel and cobbles. The gravel portion of the topsoil-gravel admixture material shall be a screened product and have a maximum particle size of less than 1-inch. The topsoil portion of the topsoil-gravel admixture material will consist of select material from the on-site topsoil borrow area.

Gradation specifications for the gravel used for topsoil-gravel admixture material shall be confirmed by gradation testing prior to mixing with the topsoil, to determine the maximum particle size. Testing shall consist of particle-size distribution testing (ASTM D422) at a frequency of at least one test per 2,000 cubic yards of rock delivered to the site, or when rock characteristics show a significant variation.

Gradation specifications for topsoil-gravel admixture material shall be confirmed by gradation testing, on samples collected from the point of placement (on the topdeck). Testing shall consist of particle-size distribution testing (ASTM D422) at a frequency of at least one test per 2,000 cubic yards of mixture placed, or when the characteristics of the mixture show a significant variation.

Layer thickness of the topsoil-gravel admixture will be controlled through establishment of grade stakes placed on a 200 x 200 foot grid on the top of the cells and by a 100 x 100 foot grid on the cell slopes. Physical checks of topsoil-gravel admixture depth will be accomplished through the use of hand dug test pits at the center of each grid in addition to monitoring the depth indicated on the grade stakes.

5.6.2 Material Placement

QC Technicians will observe the surface condition prior to fill placement. If the compacted surface of any layer of fill is too dry or smooth to bond properly with the layer of material to be placed thereon, it will be moistened and/or reworked with a harrow, scarifier, or other suitable equipment to a sufficient depth to provide relatively uniform moisture content and a satisfactory bonding surface before the next successive layer of fill is placed. If the compacted surface of any layer of fill is too wet (due to precipitation) for proper compaction of the fill material to be placed thereon, it will be reworked with harrow, scarifier or other suitable equipment to reduce the moisture content to the required level. It will then be recompacted to the specified requirements.

Nesting of oversized material will be controlled through selective excavation of stockpiled material, observation of placement by QC Technicians with authority to stop work and reject material being placed and by culling oversized material from the fill utilizing a grader. Successive loads of material will be placed on the fill so as to produce the best practical distribution of material.

QC Technicians will monitor the weather and temperature conditions. No material will be placed when the fill material or the underlying material is frozen or when ambient temperatures do not permit the placement or compaction of the materials to the specified density without developing frost lenses in the fill.

QC Technicians will monitor and document lift thicknesses frequently to ensure the Technical Specifications are being met. The required layer and lift thicknesses are listed in Table 7.

Table 7 - Summary of Cover Component Layer and Lift Thicknesses

Cover Component	Layer Thickness	Lift Thickness
Interim Fill	30 in. (min.)	12 in. loose (max.)
Compacted Cover Layer	36 to 48 in. (min.)	12 in. loose (max.)
Growth Medium Layer	42 in. (min.)	18 in. loose (max.)
Erosion Protection Layer	6 in. (min.)	6 in. (max.)

5.6.3 Density Control

The QC Technicians will monitor placement, moisture conditioning, and compaction of the fill as it is placed. Prior to the start of field compaction operations, appropriate laboratory compaction curves will be obtained for the range of materials to be placed. Laboratory compaction curves based on complete Proctor tests will be conducted at the frequencies outlined in Table 8, depending on the variability of materials being placed.

Each layer of the fill will be conditioned so that the moisture content is uniform throughout the layer prior to and during compaction. Each lift will be compacted by a sufficient number of roller passes or other compaction equipment to achieve the required dry density. Material that does not meet the required dry density will be rejected and will be reworked until the dry density is within the specified limits. Reworking may include removal, re-harrowing, reconditioning, re-rolling, or combinations of these procedures.

The required testing frequencies are included in Table 8. For all layers requiring compaction testing, a minimum of two tests will be taken for each day that an applicable amount of fill is placed in excess of 150 cubic yards. A minimum of one test per lift and at least one test for every full shift of compaction operations will be taken.

Table 8 - Summary of Cover Component Density Testing Frequencies and Requirements

Cover Component	Compaction Test Frequency	Relative Compaction Requirement*	Proctor Frequency
Compacted Cover Layer	1/500 cubic yards placed	95% (min.)	1/5,000 cubic yards placed
Growth Medium Layer	1/2,000 cubic yards placed	85% (min.)	1/10,000 cubic yards placed

* Based on maximum dry density and optimum water contents as determined by standard Proctor tests (ASTM D698 Method A or C) on the same material.

Field density testing may be conducted with the sand cone test (ASTM D1556) or a nuclear density gauge (ASTM D6938, or as modified by the QA Manager). Correlation of nuclear density gauge results shall be by comparison with results from sand cone test(s) and laboratory testing for water content(s) using the oven drying method (ASTM D2216) on similar material. A sufficient number of sand cone tests and moisture content tests will be performed to provide a correlation between the sand cone and nuclear density tests. Field density tests shall be compared with standard Proctor tests (ASTM D698 Method A or C) on the same material. Rock corrections (ASTM D4718) for oversize particles may be required for the topsoil-gravel admixture material (or other materials) depending on the gradation of the gravel material selected.

The actual frequency of testing may be increased by the CQA Site Manager if variability of materials is noted at the site, during adverse conditions, or to isolate failing areas of the construction.

5.6.4 Surface Slopes and Grades

The final cover surface shall have maximum side slopes of 5:1 and a top surface sloping in the direction and grade shown on the Drawings. The side slopes and top surface shall be free from abrupt changes in grade or areas of runoff concentration. The perimeter apron at the toe of the side slopes shall have a minimum width of 20 feet from the toe of the side slopes and slope away from the toe of the side slopes (as shown on the Drawings).

5.6.5 Tolerances

The completed cover surface shall be constructed to within 1.0 foot (horizontally) of the lines as designed, and within 0.1 foot (vertically) of the elevations as designed. The final surface of the cover shall be smoothed to avoid abrupt changes in surface grade. The layer thicknesses shall meet the required minimum thicknesses identified in the Technical Specifications and Drawings.

5.6.6 Nonconformance, Corrective Action and Stop Work

The CQA Site Manager and QC Technicians will have the authority to reject material that is brought to the site or material that has been placed. For a failed field density test, the QC Technician will determine the extent and depth of the affected area and require the Contractor to re-work the material as described above. If persistent failed tests occur (indicating inadequate compaction methods), the CQA Site Manager will have the authority to stop the work until the underlying cause is determined and the Contractor can demonstrate that the moisture/density specifications can be met.

5.6.7 Documentation

All field and laboratory test results, observations of fill placement, and field compaction test results will be recorded using the appropriate field forms and reports, as described in Section 4. Table 9 includes a summary of the required materials testing and frequencies for the cover components.

Table 9 - Summary of Testing Frequency and Criteria for Cover Components

Component	Test	ASTM Standard	Frequency	Criteria
Random Fill (compacted cover & growth medium layers)	Gradation with 200 Wash	D422	1/2,000 cubic yards	Max. Particle = 6 inches, Min. 10% passing the No. 200 sieve
Rock Mulch	Gradation	D422	1/2,000 cubic yards	$D_{100} \leq 1$ inch

5.7 Riprap and Filter Material

The side slopes of the reclaimed cover will be protected by riprap surfacing. The size, thickness and gradation requirements for the riprap are provided in the Drawings and Technical Specifications.

5.7.1 Material Conformance Monitoring and Testing

Riprap will be a screened product transported from aggregate sources north of the project site. The CQA Contractor will perform monitoring and frequent verification testing to confirm that the riprap meets the gradation and durability specifications.

During active riprap placement, each load of material will be visually checked against standard piles for gradation prior to transport to the tailings cells.

5.7.1.1 Riprap

Material for the perimeter aprons and side slopes will consist of granular materials from approved off-site areas. Riprap shall meet NRC long-term durability requirements (rock quality designation of 65 or more; Johnson, 2002).

Riprap shall be a screened product, free from roots, branches, rubbish, and debris. The specifications as given below are for rock quality designations of 70 or higher. If actual rock quality designation is between 65 and 69, additional oversizing will be required. Rock quality designations below 65 will not be acceptable.

Designated gradations for the riprap will be specified on the final drawings for construction. Riprap will be imported from off-site.

- Side slope riprap shall have a minimum D_{50} as listed below and a minimum layer thickness of 1.5 times the D_{50} or the D_{100} of the riprap, whichever is greater:
    - 1.7 in. for non-accumulating flow side slopes
    - 5.3 in. for Cell 4A and Cell 4B southern side slopes
    - 4.5 in. for Cell 1 Disposal Area side slope

- Riprap used in the rock aprons shall have a minimum D_{50} as listed below and a minimum layer thickness of 1.5 times the D_{50} or the D_{100} of the riprap, whichever is greater:
    - 3.4 in. for Rock Apron A
    - 10.5 in. for Rock Apron B
    - 9.0 in. for Rock Apron C

Material specifications for the riprap shall be confirmed by gradation testing conducted by the CQA Laboratory. Testing shall consist of particle-size distribution testing (ASTM D422) at a frequency of at least one test per 10,000 cubic yards of rock delivered to the site, or when rock characteristics show a significant variation.

Riprap layer thickness will be controlled through establishment of grade stakes placed on a 200 x 200 foot grid on the top of the cells and by a 100 x 100 foot grid on the cell slopes. Physical checks of riprap depth will be accomplished through the use of hand dug test pits at the center of each grid in addition to monitoring the depth indicated on the grade stakes.

Test series for rock durability will include specific gravity, absorption, sodium soundness and LA abrasion. During construction additional test series and gradations will be performed for each type of riprap when approximately one-third (1/3) and two-thirds (2/3) of the total volume of each type have been produced or delivered. For any type of rock where the volume is greater than 30,000 cubic yards, a test series and gradations will be performed for each additional 10,000 cubic yards of rock produced or delivered. Gradation tests will also be performed at the direction of the QC Technician for any locations considered inadequate based on visual inspection by the QC Technician, or if difficulties are experienced by the Contractor during rock placement.

5.7.1.2 Filter Material

Filter material shall be free from roots, branches, rubbish, and debris. Filter material will generally be classified as sand containing gravel and fines and shall meet the following gradation specifications.

Table 10 – Filter Material Gradation

Sieve Size	Percent Passing, by Weight
3-inch	100
No. 4	70-100
No. 20	40-60
No. 200	0-5

Material specifications for the filter material shall be confirmed by gradation testing conducted by the CQA Laboratory. Testing shall consist of particle-size distribution testing (ASTM D422) at a frequency of at least one test per 10,000 cubic yards of filter material delivered to the site, or when material characteristics show a significant variation.

Filter layer thickness will be established during construction with grade stakes placed on a grid or centerline and offset pattern and layer thickness marks on each grade stake. The minimum thickness of the layer will be verified by spot checking of layer thickness by hand excavation in selected locations.

5.7.2 Material Placement

QC Technicians will monitor riprap placement. An initial section of each type of riprap constructed shall be visually examined and used to evaluate future placement. The initial section will be constructed with material meeting gradation and riprap thickness requirements. Initial testing should be conducted to determine the gradation and the rock weight/unit volume that will be achieved in future rock placement activities. Riprap material will be hauled to the reclaimed surfaces and placed on the surfaces using belly dump highway trucks and road graders. Riprap will be dumped in windrows and the grader will spread the riprap in a manner to minimize segregation of the material. Depth of placement will be controlled through the establishment of grade stakes. Minimum required thicknesses for riprap and filter material layers are provided in the Technical Specifications and Drawings. Physical checks of riprap depth will be accomplished through the use of hand dug test pits at the center of each grid in addition to monitoring the depth indicated on the grade stakes. The Contractor will excavate the test pits, and QC Technicians will observe and document the excavation. Placement of riprap will avoid accumulation of riprap sizes less than the minimum D_{50} size and nesting of the larger sized rock. Additional riprap placement requirements include:

- Individual stones shall not be greater than 90 percent of the riprap layer thickness.
- Dumped riprap shall be placed to its full course thickness in one operation and in such a manner as to avoid displacing bedding material.
- Hand placement or rearrangement of individual stones will be required only to the extent necessary to secure the results specified above. Larger stones may require individual placement by equipment.
- Any stones that are not firmly wedged shall be adjusted and additional selected stones inserted or existing stones replaced, so as to achieve a solid interlock.

5.7.3 Compaction

QC staff will monitor riprap placement. The riprap layer will be compacted by at least two passes by a D7 Dozer, tamping with the bucket of a trackhoe, or equivalent methods in order to key the rock for stability.

5.7.4 Tolerances

The completed riprap shall be placed to within 5.0 foot (horizontally) of the layout as designed, and within 0.5 foot (vertically) of the elevations as designed. The rock layer thicknesses shall meet the minimum requirements. Minimum required thicknesses for riprap and filter material layers are provided in the Technical Specifications and Drawings. Riprap layer thickness will be directly measured as outlined in Section 5.7.2. A measurement device (i.e. tape measure) may be used to determine the distance from the top of the bedding or filter layer to the top of the riprap layer.

5.7.5 Nonconformance, Corrective Action and Stop Work

The CQA Site Manager and QC Technicians will have the authority to reject riprap that is brought to the site or riprap that has been placed. For rejected riprap, QC Technicians will identify the extent of inadequate riprap and will require the Contractor to excavate the material and place additional riprap. If persistent failed tests occur (indicating inadequate placement methods), the CQA Site Manager will have the authority to stop the work until the underlying cause is determined and the Contractor can demonstrate that the riprap can be placed according to the Technical Specifications.

5.7.6 Documentation

All field and laboratory test results, observations of riprap placement, and field compaction test results will be recorded using the appropriate field forms and reports, as described in Section 4. Table 11 includes a summary of the required materials testing and frequencies for the erosion protection materials.

Table 11 - Summary of Testing Frequency and Criteria for Riprap and Filter Material

Component	Test	ASTM Standard	Frequency	Criteria
Riprap*	Gradation with 200 Wash	D422	1/10,000 cubic yards	D_{50} and Durability*
Filter Material	Gradation with 200 Wash	D422	1/10,000 cubic yards	See Table 10

*Rock durability testing per section 5.7.1.1

5.8 Protection of Soil Stockpiles

The Contractor shall maintain proper erosion control measures for stockpiles and may be required to cover piles in situations where precipitation is anticipated. The CQA Site Manager should document improper stockpile management in situations where the integrity of the material is affected. The Construction Manager and/or the CQA Officer should determine corrective measures.

ATTACHMENT C

COST ESTIMATES FOR RECLAMATION OF WHITE MESA FACILITY IN BLANDING, UTAH

Cost Summary

WHITE MESA MILL RECLAMATION COST ESTIMATE
June 2016
Revision 5.1

Mobilization		$553,834
Office Facilities		$106,224
Mill Decommissioning		$2,296,874
Cell 1		$1,009,743
Cell 2		$1,092,353
Cell 3		$2,067,154
Cell 4A		$1,372,956
Cell 4B		$1,499,557
Management/Legal Support		$2,422,560
Miscellaneous		$2,055,680
Subtotal Direct Costs		$14,476,933
Profit Allowance	10.00%	$1,332,260
Contingency	25.00%	$3,325,170
Licensing & Bonding	2.00%	$289,539
UDEQ Contract Administration	4.00%	$579,077
Engineering Design Review	2.25%	$325,731
Contractors Equipment Floater		$82,250
Automobile and General Liability Insurance		$177,500
Long Term Care Fund		$876,425
Total Reclamation		$21,464,885
Revised Bond Amount		$21,464,885

Mill Decommissioning

TOTAL MILL DECOMMISSIONING **$2,296,874**

Reviewed 2/25/16

1) Removal of contaminated material from Mill Yard

Assume:

-- 18 inches (1.5 feet) will have to be removed
-- Area (from CAD takeoff) = 1,643,453 sq. feet
37.7 acres

Therefore: Volume moved = [1,643,453 x 1.5] / 27 = 91,303 cubic yards
(use 91,300)

91,300 / 355 cubic yards per hour = 257 machine hours

Haul route H

2) Removal of contaminated material from Ore Pad

Assume:

-- 18 inches (1.5 feet) will have to be removed
-- Area (from CAD takeoff) = 976,780 sq. feet
22.4 acres

Therefore: Volume moved = [976,780 x 1.5] / 27 = 54,266 cubic yards
(use 54,300)

54,300 / 287 cubic yards per hour = 189 machine hours

Haul route H

3) Demolition Equipment

- Kamatsu PL400 (or Cat equivalent) with LaBounty Sheers (hydraulic)
- Cat 365 Trackhoe with Grapples
- Cat 770 Rock Trucks (4 each)
- Cat 988 Loader (1 each)

4) Demolition Crew

- Heavy Equipment Operators - PC400, Cat 365, Cat 988
- Dust Control - 2 Laborers
- Mechanics - Cut debris to reduce/avoid oversize and voids - 4 each
- Truck Drivers - 4 each

5) Tool and Expendable Allowance, covering the following items:

- -- Safety gear and supplies
- -- Hand tools
- -- Bottled Gases and Torches
- -- Allow $1.30 per man-hour for all but Heavy Equipment Operators and Truck Drivers

6) Demolition Time Estimates

-- Mill Building	20 Days
-- Ore Bin	2 Days
-- CCD, Pre-Leach, Claricone	5 Days
-- Sample Plant	1 Day
-- Boiler House	5 Days
-- Vanadium EMF/Ox	2 Days
-- Shop/Warehouse	4 Days
-- Office/Lab Building	3 Days
-- Misc. & Bone Yard	4 Days
-- Decon Pads (2)	2 Days

7) Foundation Demolition

-- Assume area of structure times $3.30 per square foot

	Area, sq ft	$ Cost
Mill Building	37,500	$ 123,750
SX Building	55,970	$ 184,701
CCD, Pre-Leach, Claricone	15,000	$ 49,500
Shop/Warehouse	19,300	$ 63,690
Office*	12,100	$ 15,125
Sample Plant	4,200	$ 13,860
Vanadium EMF/Ox	1,200	$ 3,960
Boiler house	2,900	$ 9,570
Decon Pads	1,350	$ 4,455

-- Labor at $2.75, Equipment at $0.55

-- * Labor at $0.70, Equipment at $0.55

8) Revegetation

Assume:

-- Mill Yard Area	1,643,453	sq. feet
-- Ore Pad Area	976,780	sq. feet

-- Place 6 inches of Topsoil

[1,643,453 976,780] sq.feet x 0.5 feet] / [27 cubic feet / cubic Yard] 48,523 cu yds

Use 48,600 Cubic Yards

48,600 / 279 cu yds per hour = 174 Scraper hours

Seeding

RS Means Referance 32 92 19 14 0500	=	$25.50 / 1 thousand sq.ft.
50 acres	=	2178 thousand sq.ft.

9) Removal of Nitrate and Ammonium Sulfate Contaminated Soil
and Concrete Cover Required by Phase 1 of the Nitrate CAP

Assume:

-- 222 inches (18.5 feet) will have to be removed over the entire excavated area as delineated by the proposed excavation contours in Attachment 4-1 to the December 2013 White Mesa Uranium Mill Proposal for Remediation, 2012 Phase 1 of Final Nitrate Corrective Action Plan, May 7, and Stipulation and Consent Order of December 12, 2012 Docket No. UGW-12-04
-- This depth corresponds to 20 feet minus the 18 inches associated with the Mill Yard and Ore Pad reclamation.
-- The nitrate and ammonium sulfate contamination is located within the Mill Yard and Ore Pad which will both have the top 18 inches removed during reclamation as addressed in above in item 1 and 2.
-- Production is limited by the trucking fleet and not the loader.
-- The dozer will assist the loader during the soil removal.
-- The dozer will backfill and grade the excavation area after the contaminated soil has been removed.
--Volumes and areas are taken from CAD and shown on Attachment 4-1.
--RS Means reference 02 41 13 17 5300 was used to estimate the costs. $2.15 per square foot.

--Excavation Area (from CAD takeoff) =	83,641	sq. feet
-- Concrete Cover Area (from CAD takeoff)	27,500	sq. feet

-- Volume (from CAD takeoff) =	47,676	Cubic Yards
-- Volume including a 200% Conservatism Factor	95,352	Cubic Yards

95,352	/ 285 cubic yards per hour =	335	Trucking Hours
95,352	/ 685 cubic yards per hour =	139	Backfilling Hours
	Haul route H		

10) Asbestos Removal

See the attached Executive Summaries from the Asbestos Inspection Reports.

Volume Calculation - Cell 1

Reviewed 2/25/16

1) Area of Cell 1 - 2,575,703 sq ft = 59.13 acres

2) Crystal and Liner Cover Removal
- Dewatering estimated at 2 years based on the last time Cell 1 was dry and approximate duration.
- Crystal thickness assumed as 1.5 feet.
- Soil Cover over the PVC Liner is based on design and as-built - 1.5 feet.
- Crystal and soil cover will be excavated at the same time and placed in Cell 4A.
- Crystal and soil cover will be windrowed with a dozer, and loaded into 3 trucks with a loader.
- The PVC Liner will cut into manageable pieces and loaded into a truck with a hydraulic excavator.
- Road maintenance will be accomplished with a motorgrader and water wagon.

$$\text{Volume to be removed} = \frac{2{,}575{,}703 \times (1.5\text{ ft} + 1.5\text{ ft})}{27\text{ ft}^3/\text{cy}} \quad \boxed{286{,}189 \text{ CY}}$$

3) Removal of Contaminated Material Under Liner
- Estimated depth of contaminated soil required to be removed - 1 foot.
- Contaminated material will be removed to Cell 4A.
- Contaminated soil will be windrowed with a dozer, and loaded into 3 trucks with a loader.
- Road maintenance will be accomplished with a motorgrader and water wagon.

$$\text{Volume to be removed} = \frac{2{,}575{,}703 \times (1\text{ ft})}{27\text{ ft}^3/\text{cy}} \quad \boxed{95{,}396 \text{ CY}}$$

4) Construct Channel
- The channel will be constructed in the southwest corner of Cell 1 and will daylight to an existing natural channel.
- The channel requires blasting of the bedrock to achieve the design grade.
- Approximate dimensions of the channel are 1,200 feet long by 150 feet wide by 10 feet deep.

$$\text{Volume to be removed} = \frac{1{,}200\text{ ft} \times 150\text{ ft} \times 10\text{ ft}}{27\text{ ft}^3/\text{cy}} \quad \boxed{66{,}667 \text{ CY}}$$

- The broken rock material will be loaded into 3 trucks with a hydraulic excavator.
- 23,188 CY of this material will be used in Cell 1 to grade the side slopes from 3H:1V to 5H:1V.
- The remainder of the excavated material will be hauled to Cell 4A South Slope and used as Random Fill - 43,479 CY.

5) Grade Side slopes
- Material needed to grade the side slopes of Cell 1 will be produced during the construction of the Cell 1 Drainage Channel
- The costs for staging the grading material at the base of the slopes is accounted for thin the Channel Construction Task.
- The slopes will be graded and shaped with a dozer.
- Cell 1 has 6,020 feet of slopes. The slopes are 8 feet high and currently at a 3H:1V slope.

$$\text{Volume needed for Grading} = \frac{6{,}020\text{ ft} \times 8\text{ ft} \times 26\text{ ft} \times (1/2)}{27\text{ ft}^3/\text{cy}} \quad \boxed{23{,}188 \text{ CY}}$$

6) Topsoil Application

- 29 acres of Cell 1 requires placement of 6 inches of topsoil.
- The remainder of Cell 1 will be covered with exposed Dakota Sandstone or Rip Rap.
- The topsoil will hauled from Topsoil pile W4.
- A scraper fleet will haul the topsoil and a dozer will assist with loading and final spreading.
- Road maintenance will be accomplished with a motorgrader and water wagon.

$$\text{Volume needed for be placed} = \frac{29 \text{ acres x } 43{,}560 \text{ ft2 /acre x } 0.5 \text{ ft}}{27 \text{ ft}^3\text{/cy}} \quad \boxed{23{,}393 \quad \text{CY}}$$

7) Rock Armor and Rip Rap Filter Placement

- Rock for side armor, top armor and toe aprons will come from an off-site gravel source one (1) mile north of Blanding. Rock will be produced through screening, stockpiled and trucked to the site at the time of use. Belly dump trucks will dump gravel in windrows on the top and sides of the Cell.
- A dozer will spread the delivered rock.
- Road maintenance will be accomplished with a motorgrader and water wagon.
- 8,607 CY of rock will be placed.

Quality Control

Resource Description	Units	Cost/Unit	Task Units	Task Cost
Quality Control Contractor	hrs	$62.00	600	$37,200

Total Quality Control **$37,200**

TOTAL RECLAMATION OF CELL 2 **$1,092,353**

Volume Calculation - Cell 2

Reviewed 02/25/16

1) Area of Cell 2 - 2,986,660 sq ft = 68.56 acres

2) The bridging layer of the cover has already been placed over the entire Cell 2 surface.

3) Assumptions

- Cell will be graded to Design elevation utilizing finer materials in random fill stockpiles and from "clay" stockpiles.
-Dewatering Estimated at 12 years based on the Cell 2 2013 drawdown(1 foot/ year) and remaing solution depth (12 feet).

"- Radon Barrier has been placed over the entire Cell"

- The upper 1 foot of random fill will be placed utilizing the fine random fill and clay stockpiles

- Rock for side armor, top armor and toe aprons will come from an off-site gravel source one (1) mile north of Blanding. Rock will be produced through screening, stockpiled and trucked to the site at the time of use. Belly dump trucks will dump gravel in windrows on the top and sides of the Cell.

5) Bring Platform Fill up to Design elevation (Lower Random) **COMPLETE**
Assume full area of Cell X one (1) foot thick

2,986,660 sq ft X 1 ft. / 27 cubic feet per cubic yard = cubic yards

Use cubic yards

6) Placement of Clay Layer (One (1) foot thick on top of Cell only) **DELETED**
Assume full area of Cell X one (1) foot thick

2,986,660 sq ft X 1 ft. / 27 cubic feet per cubic yard = cubic yards

Use cubic yards

7) Upper Random Fill Volume - Top of Cell area
Assume full area of Cell X two (2) foot thick
- An excavator and loader will load 4 trucks.
- The dozer will place the material, water truck will moisture condition and the compactor will compact the material.
- The water wagon and grader will maintain the haul road.

2,986,660 sq ft X 2 ft. / 27 cubic feet per cubic yard = 221,234 cubic yards

Use **221,300 cubic yards**

8) Armor Protection - Top of Cell
Assume full area of Cell X one-half (0.5) foot thick

2,986,660 sq ft X 0.5 ft. / 27 cubic feet per cubic yard = 55,309 cubic yards

Use **55,400 cubic yards**

9) Cell 2 North Slope (Slope #1) common with Cell 1-I

Average height	12	feet
Length	2600	feet

a) Random fill to reduce slope from 3:1 to 5:1

First Wedge [12 X 12 X 5)/2 - (12 X 12 X 3)/2] X 2600

= 374,400 cubic feet/ 27 = 13,867 cubic yards

Use **13,900 cubic yards**

Remaining Random Fill

[15 X 15 X 5)/2 - (12 X 12 X 5)/2] X 2600

= 526,500 cubic feet/ 27 = 19,500 cubic yards

Use **19,500 cubic yards**

Total Random Fill North Slope **33,400 cubic yards**

b) Rock Armor 8" thick - 0.67 feet

[15.67 X 15.67 X 5)/2 - (15 X 15 X 5)/2] X 2600

= 133,568 cubic feet/ 27 = 4,947 cubic yards

Use **5,000 cubic yards**

c) Rip Rap Filter 6" thick - 0.5 feet

[15.5 X 15.5 X 5)/2 - (15 X 15 X 5)/2] X 2600

= 99,125 cubic feet/ 27 = 3,671 cubic yards

Use **3,700 cubic yards**

d) Toe Apron — 2 X 7 X 2600 / 27 = 1,348 cubic yards

Use **1,400 cubic yards**

Total Rock Armor Cell 2 north Slope — **6,400 cubic yards**

10) North Slope common with Mill yard (Slope #2)

Average height	1	feet
Length	900	feet

a) Random fill to reduce slope from 3:1 to 5:1

First Wedge [1 X 1 X 5)/2 - (1 X 1 X 3)/2] X 900

= 900 cubic feet/ 27 = 33 cubic yards

Use **100 cubic yards**

Remaining Random Fill

[4 X 4 X 5)/2 - (1 X 1 X 5)/2] X 900

= 33,750 cubic feet/ 27 = 1,250 cubic yards

Use **1,300 cubic yards**

Total Random Fill North Slope — **1,400 cubic yards**

b) Rock Armor 8" thick - 0.67 feet

[4.67 X 4.67 X 5)/2 - (4 X 4 X 5)/2] X 900

= 13,070 cubic feet/ 27 = 484 cubic yards

Use **500 cubic yards**

c) Rip Rap Filter 6" thick - 0.5 feet

[4.5 X 4.5 X 5)/2 - (4 X 4 X 5)/2] X 900

= 9,563 cubic feet/ 27 = 354 cubic yards

Use **350 cubic yards**

d) No Toe Apron on fill common with Mill Yard

Total Rock Armor on slope common to Mill Yard — **500 cubic yards**

11) Cell 2 West Dike (Slope #3)

Average height 2 feet
Length 500 feet

a) Random fill to reduce slope from 3:1 to 5:1

First Wedge [2 X 2 X 5)/2 - (2 X 2 X 3)/2] X 500

= 2,000 cubic feet/ 27 = 74 cubic yards
Use 100 cubic yards

Remaining Random Fill

[2 X 2 X 5)/2 - (2 X 2 X 3)/2] X 500

= 2,000 cubic feet/ 27 = 74 cubic yards
Use 100 cubic yards

Total Random Fill North Slope 200 cubic yards

b) Rock Armor 8" thick - 0.67 feet

[5.67 X 5.67 X 5)/2 - (5 X 5 X 5)/2] X 500

= 8,936 cubic feet/ 27 = 331 cubic yards
Use 400 cubic yards

c) Rip Rap Filter 6" thick - 0.5 feet

[5.5 X 5.5 X 5)/2 - (5 X 5 X 5)/2] X 500

= 6,563 cubic feet/ 27 = 243 cubic yards
Use 250 cubic yards

d) Toe Apron Not required for slope 10 feet long - Drainage from Cell goes south to Cell 3 and then off of south slope of Cell 3

Total Rock Armor Cell 2 north Slope 400 cubic yards

12) Cell 2 East Dike (Slope #4)

Average height 1 feet
Length 1250 feet

a) Random Fill Wedge from #10 1 cubic foot per linear foot X 1250 46 cubic yards
Use 100 cubic yards

b) Remaining Random Fill from #10

37.5 cubic foot per linear foot X 1250 / 27 — 1,736 cubic yards

Use **1,800 cubic yards**

Total Random Slope #4 — **1,900 cubic yards**

c) Rock Armor 8" thick - 0.67 feet from #10 14.52 cubic feet per linear foot of dike

14.52 cubic foot per linear foot X 1250 / 27

= 18,150 cubic feet/ 27 = 672 cubic yards

Use **675 cubic yards**

d) Rip Rap Filter 6" thick - 0.5 feet

9.075 cubic foot per linear foot X 1250 / 27

= 420 cubic feet/ 27 = 420 cubic yards

Use **420 cubic yards**

e) Toe Apron Not required

Total Rock Armor Cell 2 north Slope — **675 cubic yards**

13) South Slope Cell 2 common with Cell 3 (Slope #5)

Average height 3 feet
Length 3500 feet

a) Random fill to reduce slope from 3:1 to 5:1

Random Fill [3 X 3 X 5)/2 - (3 X 3 X 3)/2] X 3500

= 31,500 cubic feet/ 27 = 1,167 cubic yards

Use **1,200 cubic yards**

Random Fill Upper

[6 X 6 X 5)/2 - (4 X 4 X 5)/2] X 3500

= 175,000 cubic feet/ 27 = 6,481 cubic yards

Use **6,500 cubic yards**

b) Clay Layer

[4 X 4 X 5)/2 - (3 X 3 X 5)/2] X 3500

= 61,250 cubic feet/ 27 =		2,269	cubic yards
	Use	2,300	cubic yards

c) Rock Armor 8" thick - 0.67 feet

[6.67 X 6.67 X 5)/2 - (6 X 6 X 5)/2] X 3500

= 74,278 cubic feet/ 27 =		2,751	cubic yards
	Use	2,800	cubic yards

c) Rip Rap Filter 6" thick - 0.5 feet

[6.5 X 6.5 X 5)/2 - (6 X 6 X 5)/2] X 3500

= 54,688 cubic feet/ 27 =		2,025	cubic yards
	Use	2,050	cubic yards

No Toe Apron

Total Rock Armor on slope Cell 2 Slope common to Cell 3 — 2,800 cubic yards

Total Quality Control **$74,400**

TOTAL RECLAMATION OF CELL 3 **$2,067,154**

Volume Calculation - Cell 3

Reviewed 02/25/16

1) Area of Cell 3 - 3,234,252 sq ft = 74.25 acres

2) Area of Cell 3 still open as of January 2015

3.0 acres Use 131,328 sq ft

3) Assumptions

- Bridging layer is placed using random fill from piles east and west of Cell 3
-Dewatering estimated at 12 years.
- Cell will be graded to Design elevation utilizing finer materials in random fill stockpiles and from "clay" stockpiles.

- Clay will be mined, blended, and hauled from borrow site location in Section 16 - four miles south of the mill area, using belly dump trucks, clay layer on top of Cell only

- The upper 1 foot of random fill will be placed utilizing the fine random fill and clay stockpiles

- Rock for side armor, top armor and toe aprons will come from an off-site gravel source one (1) mile north of Blanding. Rock will be produced through screening, stockpiled and trucked to the site at the time of use. Belly dump trucks will dump gravel in windrows on the top and sides of the Cell.

4) Bridging Layer (Platform Fill) Remaining to be placed

131,328 sq ft X 3 ft. / 27 cubic feet per cubic yard = **14,592 cubic yards**

- The cost to Blast Load and Haul the material from the Cell 1 channel is accounted for in the channel construction.

5) Bring Platform Fill up to Design elevation (Lower Random)
Assume full area of Cell X one (1) foot thick

3,234,252 sq ft X 1 ft. / 27 cubic feet per cubic yard = 119,787 cubic yards

6) Placement of Clay Layer (One (1) foot thick on top of Cell only)
Assume full area of Cell X one (1) foot thick

3,234,252 sq ft X 1 ft. / 27 cubic feet per cubic yard = 119,787 cubic yards

Use **120,000 cubic yards**

7) Upper Random Fill Volume - Top of Cell area
Assume full area of Cell X one (2) foot thick
- 4 trucks, 1 loader and 1 excavator used to load and haul the random fill.
- A dozer will spread the material, a water truck will moisture condition prior to being compacted with the compactor.
- A road grader and water wagon will maintain the haul roads.

3,234,252 sq ft X 2 ft. / 27 cubic feet per cubic yard = 239,574 cubic yards

Use **240,000 cubic yards**

8) Armor Protection - Top of Cell
Assume full area of Cell X one-half (0.5) foot thick

3,234,252 sq ft X 0.5 ft. / 27 cubic feet per cubic yard = 59,894 cubic yards

Use **60,000 cubic yards**

9) Cell 3 North Slope (Slope #6) common with Cell 2

No clay on slopes. Toe apron only at base of long slope or where drainage is directed.

Average height 2 feet
Length 1100 feet

a) Random fill to reduce slope from 3:1 to 5:1
First Wedge [2 X 2 X 5)/2] X 1100

= 11,000 cubic feet/ 27 = 407 cubic yards
Use **410 cubic yards**

Remaining Random Fill

[5 X 5 X 5)/2 - (2 X 2 X 5)/2] X 1100

= 57,750 cubic feet/ 27 = 2,139 cubic yards
Use **2,200 cubic yards**

Total Random Fill North Slope **2,610 cubic yards**

b) Rock Armor 8" thick - 0.67 feet

[5.67 X 5.67 X 5)/2 - (5 X 5 X 5)/2] X 1100

= 19,659 cubic feet/ 27 = 728 cubic yards
Use **730 cubic yards**

c) Rip Rap Filter 6" thick - 0.5 feet

[5.5 X 5.5 X 5)/2 - (5 X 5 X 5)/2] X 1100

= 14,438 cubic feet/ 27 = 535 cubic yards
Use 550 cubic yards

d) Toe Apron No rock required

Total Rock Armor Cell 3 north Slope **730 cubic yards**

10) Cell 3 South Dike, west end (Slope #7)

Average height	16 feet
Length	1750 feet

a) Random fill to reduce slope from 3:1 to 5:1

First Wedge [16 X 16 X 5)/2 - (16 X 16 X 3)/2] X 1750

= 448,000 cubic feet/ 27 = 16,593 cubic yards

Use 16,600 cubic yards

Remaining Random Fill

[19 X 19 X 5)/2 - (16 X 16 X 5)/2] X 1750

= 459,375 cubic feet/ 27 = 17,014 cubic yards

Use 17,100 cubic yards

Total Random Fill North Slope 33,700 cubic yards

b) Rock Armor 8" thick - 0.67 feet

[19.67 X 19.67 X 5)/2 - (19 X 19 X 5)/2] X 1750

= 113,351 cubic feet/ 27 = 4,198 cubic yards

Use 4,200 cubic yards

c) Rip Rap Filter 6" thick - 0.5 feet

[19.5 X 19.5 X 5)/2 - (519 X 19 X 5)/2] X 1750

= 84,219 cubic feet/ 27 = 3,119 cubic yards

Use 3,200 cubic yards

d) Rock Apron at toe of slope [2ft X 7ft wide X 1750 long] / 27 = 907

Use 1,000 cubic yards

Total Rock Armor Slope #7 5,200 cubic yards

11) Cell 3 South Dike (Slope #8) **VOLUME DELETED. AREA FILLED WITH CELL 4A TAILINGS**

a) Random Fill No existing Dike [(4 X 4 X 5) / 2] X 800 /27 = 1185 cubic yards

Use 1,200 cubic yards

Total Random Slope #4 1,200 cubic yards

b) Rock Armor 8" thick - 0.67 feet 14.52 cubic feet per linear foot of dike

14.52 cubic foot per linear foot X 800 / 27

= 430 cubic feet/ 27 = 430 cubic yards

Use 450 cubic yards

c) Rip Rap Filter 6" thick - 0.5 feet

10.84 cubic foot per linear foot X 800 / 27

= 321 cubic feet/ 27 = 321 cubic yards

Use 325 cubic yards

d) Toe Apron Not required

Total Rock Armor Cell 3 East Slope 450 cubic yards

TOTAL RECLAMATION OF CELL 4A **$1,372,956**

Volume Calculation - Cell 4A

Reviewed 2/25/16

1) Area of Cell 1,785,960 sq ft = 41.00 acres

2) Assumptions

- Bridging layer is placed using random fill from piles east of Cell 4A
- Dewatering estimated at 6 years.
- Cell will be graded to Design elevation utilizing finer materials in random fill stockpiles and from "clay" stockpiles.

- Clay will be mined, blended, and hauled from borrow site location in Section 16 - four miles south of the mill area, using belly dump trucks, clay layer on top of Cell only.

- The upper 1 foot of random fill will be placed utilizing the fine random fill and clay stockpiles

- Rock for side armor, top armor and toe aprons will come from an off-site gravel source one (1) mile north of Blanding. Rock will be produced through screening, stockpiled and trucked to the site at the time of use. Belly dump trucks will dump gravel in windrows on the top and sides of the Cell.

3) Bridging Layer (Platform Fill) Remaining to be placed

1,785,960 sq ft X 3 ft. / 27 cubic feet per cubic yard = 198,440 cubic yards

Use 198,500 cubic yards

4) Bring Platform Fill up to Design elevation (Lower Random)
Assume full area of Cell X one (1) foot thick

1,785,960 sq ft X 1 ft. / 27 cubic feet per cubic yard = 66,147 cubic yards

Use 66,000 cubic yards

5) Placement of Clay Layer (One (1) foot thick on top of Cell only)
Assume full area of Cell X one (1) foot thick

1,785,960 sq ft X 1 ft. / 27 cubic feet per cubic yard = 66,147 cubic yards

Use 66,000 cubic yards

6) Upper Random Fill Volume - Top of Cell area
Assume full area of Cell X one (2) foot thick
- 3 trucks, 1 excavator used to load and haul the random fill.
- A dozer will spread the material, a water truck will moisture condition prior to being compacted.
- A road grader and water wagon will maintain the haul roads.

1,785,960 sq ft X 2 ft. / 27 cubic feet per cubic yard = 132,293 cubic yards

Use **132,500 cubic yards**

7) Armor Protection - Top of Cell
Assume full area of Cell X one-half (0.5) foot thick

1,785,960 sq ft X 0.5 ft. / 27 cubic feet per cubic yard = 33,073 cubic yards

Use **33,000 cubic yards**

8) Cell 4A South Dike, (Slope #1)

Average heigl	36	feet
Length	1600	feet

a) Random fill to reduce slope from 3:1 to 5:1

First Wedge [36 X 36 X 5)/2 - (36 X 36 X 3)/2] X 1600

= 2,073,600 cubic feet/ 27 = 76,800 cubic yards
- 43,479 CY of material will come from the excavated channel within Cell 1. (43,479) cubic yards
- The cost to load, haul and stage the material is included in Cell 1 channel construction.

Use **33,321 cubic yards**

Remaining Random Fill

[39 X 39 X 5)/2 - (36 X 36 X 5)/2] X 1600

= 900,000 cubic feet/ 27 = 33,333 cubic yards

Use **34,000 cubic yards**

Total Random Fill South Slope **110,800 cubic yards**

b) Rock Armor 8" thick - 0.67 feet

[39.67 X 39.67 X 5)/2 - (39 X 39 X 5)/2] X 1600

= 210,836 cubic feet/ 27 = 7,809 cubic yards

Use **7,800 cubic yards**

c) Rip Rap Filter 6" thick - 0.5 feet

[39.5 X 39.5 X 5)/2 - (39 X 39 X 5)/2] X 1600

= 157,000 cubic feet/ 27 = **5,815 cubic yards**

Use **6,000 cubic yards**

d) Rock Apron at toe of slope [2ft X 7ft wide X 1600 long] / 27 = 830

Use 850 cubic yards

Total Rock Armor South Slope 8,650 cubic yards

9) Cell 4A East Slope (Slope #2)

Average heigl	8	feet
Length	1200	feet

a) Random fill to reduce slope from 3:1 to 5:1

First Wedge [8 X 8 X 5)/2 - (8 X 8 X 3)/2] X 1200

= 76,800 cubic feet/ 27 = 1185 cubic yards

Use 1,200 cubic yards

Remaining Random Fill

[11 X 11 X 5)/2 - (8 X 8 X 5)/2] X 1200

= 171,000 cubic feet/ 27 = 6,333 cubic yards

Use 6,500 cubic yards

Total Random Slope #3 7,700 cubic yards

b) Rock Armor 8" thick - 0.67 feet 14.52 cubic feet per linear foot of dike

14.52 cubic foot per linear foot X 1200 / 27

= 645 cubic feet/ 27 = 24 cubic yards

Use 25 cubic yards

c) Rip Rap Filter 6" thick - 0.5 feet

10.84 cubic foot per linear foot X 1200 / 27

= 482 cubic feet/ 27 = **18 cubic yards**

Use **20 cubic yards**

c) Toe Apron Not required

Total Rock Armor Cell 4A East Slope | 25 cubic yards

Volume Calculation - Cell 4B

Reviewed 2/25/16

1) Area of Cell 4I 1,785,960 sq ft = 41 acres

2) Assumptions

- Bridging layer is placed using random fill from piles west of Cell 4B

- Cell will be graded to Design elevation utilizing finer materials in random fill stockpiles and from "clay" stockpiles.

- Clay will be mined, blended, and hauled from borrow site location in Section 16 - four miles south of the mill area, using belly dump trucks, clay layer on top of Cell only.

- The upper 1 foot of random fill will be placed utilizing the fine random fill and clay stockpiles

- Rock for side armor, top armor and toe aprons will come from an off-site gravel source one (1) mile north of Blanding. Rock will be produced through screening, stockpiled and trucked to the site at the time of use. Belly dump trucks will dump gravel in windrows on the top and sides of the Cell.

3) Bridging Layer (Platform Fill) Remaining to be placed

1,785,960 sq ft X 3 ft. / 27 cubic feet per cubic yard = 198,440 cubic yards

Use 198,500 cubic yards

4) Bring Platform Fill up to Design elevation (Lower Random)
Assume full area of Cell X one (1) foot thick

1,785,960 sq ft X 1 ft. / 27 cubic feet per cubic yard = 66,147 cubic yards

Use 66,000 cubic yards

5) Placement of Clay Layer (One (1) foot thick on top of Cell only)
Assume full area of Cell X one (1) foot thick

1,785,960 sq ft X 1 ft. / 27 cubic feet per cubic yard = 66,147 cubic yards

Use 66,000 cubic yards

6) Upper Random Fill Volume - Top of Cell area

Assume full area of Cell X one (2) foot thick

1,785,960 sq ft X 2 ft. / 27 cubic feet per cubic yard = 132,293 cubic yards

Use **132,000 cubic yards**

7) Armor Protection - Top of Cell

Assume full area of Cell X one-half (0.5) foot thick

1,785,960 sq ft X 0.5 ft. / 27 cubic feet per cubic yard = 33,073 cubic yards

Use **33,000 cubic yards**

8) Cell 4B South Dike, (Slope #1)

Average height	36	feet
Length	1600	feet

a) Random fill to reduce slope from 3:1 to 5:1

First Wedge [36 X 36 X 5)/2 - (36 X 36 X 3)/2] X 1600

= 2,073,600 cubic feet/ 27 = 76,800 cubic yards

Use **77,000 cubic yards**

Remaining Random Fill

[39 X 39 X 5)/2 - (36 X 36 X 5)/2] X 1600

= 900,000 cubic feet/ 27 = 33,333 cubic yards

Use **34,000 cubic yards**

Total Random Fill South Slope **111,000 cubic yards**

b) Rock Armor 8" thick - 0.67 feet

[39.67 X 39.67 X 5)/2 - (39 X 39 X 5)/2] X 1600

= 210,836 cubic feet/ 27 = 7,809 cubic yards

Use **7,800 cubic yards**

c) Rip Rap Filter 6" thick - 0.5 feet

[39.5 X 39.5 X 5)/2 - (39 X 39 X 5)/2] X 1600

= 157,000 cubic feet/ 27 = **5,815 cubic yards**

Use **6,000 cubic yards**

d) Rock Apron at toe of slope [2ft X 7ft wide X 1600 long] / 27 = 830

Use 850 cubic yards

Total Rock Armor South Slope 8,650 cubic yards

9) Cell 4B West Slope (Slope #2)

Average height	8 feet
Length	1200 feet

a) Random fill to reduce slope from 3:1 to 5:1

First Wedge [8 X 8 X 5)/2 - (8 X 8 X 3)/2] X 1200

= 76,800 cubic feet/ 27 = 1185 cubic yards

Use 1,200 cubic yards

Remaining Random Fill

[11 X 11 X 5)/2 - (8 X 8 X 5)/2] X 1200

= 171,000 cubic feet/ 27 = 6,333 cubic yards

Use 6,500 cubic yards

Total Random Slope #3 7,700 cubic yards

b) Rock Armor 8" thick - 0.67 feet 14.52 cubic feet per linear foot of dike

14.52 cubic foot per linear foot X 1200 / 27

= 645 cubic feet/ 27 = 24 cubic yards

Use 25 cubic yards

c) Rip Rap Filter 6" thick - 0.5 feet

10.84 cubic foot per linear foot X 1200 / 27

= 482 cubic feet/ 27 = **18 cubic yards**

Use **20 cubic yards**

c) Toe Apron Not required

Total Rock Armor Cell 4B West Slope 25 cubic yards

Volume Summary - Cell 4B

Task 1: Operation for a 5 year period.	$	-
Task 2: Maintenance for a 5 year period.	$	4,349
Task 3: Monitoring for a 5 year period.	$	6,864
Task 4: Reporting for a 5 year period.	$	8,242
Task 5: Nitrate System Abandonment	$	3,555
Sub Total	**$**	**23,010**

Notes: The Nitrate Pumping System Operation is included in the Chloroform Pumping System Operation Costs.
There is only 1 Nitrate pumping well that is not already included in the 13 wells associated with the Chloroform Pumping System.

Maintenance is scaled from the Chloroform estimate based on the ratio of pumping wells (1 Nitrate Pumping well / 13 Chloroform Pumping Wells and 5 years instead of 10 years)

Monitoring is based on an analytical cost of $345 per quarter for 5 years.

Reporting is scaled from the Chloroform estimate based on the ratio of total wells (6 Nitrate wells / 37 Chloroform Wells and 5 years instead of 10 years)

Abandonment is scaled from the Chloroform estimate based on the ratio of total wells (6 Nitrate wells / 37 Chloroform Wells)

Chloroform Pumping System

Chloroform Pumping System - Required Surety Estimate

Task 1: Operation for a 10 year period.

Assumptions

The full Chloroform pumping and monitoring system has already been installed.
Operation will be performed by the Environmental Technician at $30.890 per hour
Environmental Technician will be local labor hired by a DWMRC Contractor. A 15% markup has been applied to the actual labor rate
Daily operation checks take 1.0 hours for 1 Environmental Technician.
Weekly operation checks take 3.0 hours for 1 Environmental Technician.
Measure Depth to Water Monthly 6 hours for 1 Environmental Technician.
Water from the chloroform pumping sysytem will be pumped to the evaporation or tailings ponds or used in the Mill process. After reclamation, the water will pumped to the Cell 2 Slimes evaporation pond. The costs associated with the Cell 2 slimes evaporation pond are included in the Miscellaneous items.
Power $0.07/KWH
Average power of each pump motor = 0.75 hp.
Average pumping time per day = 1.1 hr.

Item	Quantity	Units	Quantity	Units	Cost
Daily Operation Checks - Labor	1	Hrs/Day	365	hrs/Yr	$ 11,274
Weekly Operation Checks - Labor	3	Hrs/Wk	156	hrs/Yr	$ 4,819
Measure Depth to Water Monthly	6	Hrs/Month	72	hrs/Yr	$ 2,224
Pumping hours per well per quarter	1.1	Hrs/Day	401.5	hrs/Yr	$ 16.00
				Total per year	**$ 18,525**
				Total 10 years	**$ 185,252**

Task 2: Maintenance for a 10 year period.

Assumptions

Maintenance will be performed by the Environmental Technician at $30.890 per hour
Environmental Technician will be local labor hired by a DWMRC Contractor. A 15% markup has been applied to the actual labor rate
Pump Replacement takes 4 hours for 2 Environmental Technicians.
Average of 3 pump replacements per year. Each replacement pump costs $2,200
Flow Meter Replacement takes 2 hours for 2 Environmental Technicians.
Average of 4 flow meter replacements per year. Each replacement flow meter costs $245
Heat lamp bulb replacement labor is included in daily operational checks.
Average of 14 heat lamp bulb replacements per year. Each bulb cost $10
Average of 3 pipeline freezing per year.
Clearing of a pipeline freeze takes 8 hours for 2 Environmental Technicians. No material costs.

Item	Quantity	Units	Labor Hours / Year	Material Cost per year	Cost
Pump Replacement	3	Replaced / year	24	6600	$ 7,341
Flow Meter Replacement	4	Replaced / year	16	980	$ 1,474
Heat Lamp Replacement	14	Replaced / year	0	140	$ 140
Frozen Pipeline Clearing	3	Clearing / year	48	0	$ 1,483
				Total	**$ 10,438**
				Total 10 years	**$ 104,382**

Task 3: Monitoring for a 10 year period.

Assumptions

Analytical cost per sample = $169
45 samples per quarter
Sample collection will be performed by an Environmental Technician and a Contractor Field Geologist
Environmental Technician = $31.89 per hour. Field Geologist = $90.00 per hour
Environmental Technician will be local labor hired by a DWMRC Contractor. A 15% markup has been applied to the actual labor rate
Sample collection requires 80 hours for 2 Environmental Technicians per quarter.

Item	Quantity	Units	Quantity	Unit	Cost
Analytical Costs	180	Samples/year	$ 169	$/Sample	$ 30,420
Sampling Labor - Environmental Technician	320	Hrs/year	$ 30.89	$/hr	$ 9,884
Sampling Labor - Field Geologist	320	Hrs/year	$ 90.00	$/hr	$ 28,800
Field Geologist - Travel Costs	40	Days/year	$ 180.00	$/day	$ 7,200
				Total	**$ 76,304**
				Total 10 years	**$ 763,044.67**

Task 4: Reporting for a 10 year period.

Assumptions

Reporting will be performed by the Environmental Technician at $30.890 per hour
Environmental Technician will be local labor hired by a DWMRC Contractor. A 15% markup has been applied to the actual labor rate
Report preparation is expected to take 40 hours for the Environmental Technician to complete each quarter.
Quarterly analysis of contamination extent is estimated to cost $3,000.

Item	Quantity	Units	Quantity	Unit	Cost
Report Preparation	160	Hrs/year	$ 30.89	$/hr	$ 4,942
Contamination Analyisis	4	per year	$ 3,000.00	$/Quarter	$ 12,000
				Total 10 years	**$ 101,653**

Task 5: Chloroform System Abandonment

Assumptions

Pumps and well head enclosures will be loaded on a flat bed truck by hand.
Abandonment will be performed by the Environmental Technician at $30.890 per hour
Wells will be abandoned in accordance with State of Utah Administrative Code R655-4 subsection 14.9
Flatbed truck with operator costs $55/hr.
Assumed 1 hour of labor to remove each pump and enclosure.
The materials will be discarded in the active trash area of the tailing cells if available or in an off-site landfill.
Well casing will be cut off 2 feet below the ground level.
The well will be abandoned by filling will Hole Plug.
Hole Plug Material cost estimated at $2 per foot of well.
Average well depth of 120 feet.
There is 2,600 feet of underground electrical line and 3,850' of pipeline
The HDPE pipeline and power line will be uncovered with a 365 Excavator
The 365 Excavator is estimated to excavate or backfill 412 feet per hour.
The 365 Excavator costs $155/hr without the operator.
The Excavator will also backfill the trench after the pipe has been removed.
Assumed 8 hours to place the pipeline and powerlines in the tailing cell.

Item	Quantity	Units	Labor Hrs	Equipment Hours	Total Cost
Pull pumps and remove enclosures	13	Pumping Wells	13	13	$ 1,116.56
Abandon All Wells - Labor	38	Wells	38	0	$ 1,173.78
Abandon All Wells - Materials	38	Wells	0	0	$ 9,120.00

Rock Production

ROCK PRODUCTION COST

Assumptions:
Rock is obtained from gravel source north of Blanding, Utah. BLM Public Pit
Rip Rap Rock is processed by screening only, no crushing is required, 1.25 CY of feed for 1 CY of product
Filter material is produced from Rip Rap reject
Rock is produced and stockpiled at the site
Site is 7 road miles from the mill; 6 miles of which is paved public highway
Rock will be hauled in 22 CY bellydump trucks, contract haulers ($100.00/hr)
Rock will be dumped in windrows on Tailings Cells by trucks, spread by grader, and spread by D7 Dozer
Trucks can average 30 MPH (1.75 rounds/hr)

	Product Required (CY)	Reject Factor	Material Feed to Plant (CY)	Plant Throughput (CY/hr)	Plant Operating Hours
Rip Rap material fed to plant	189,000	25.0%	236,250	122	1,900
Filter material fed to plant	25,500	10.0%	28,050	122	200
	214,500				2,100

PRODUCTION OF RIPRAP

Resource Description	Units	Cost/Unit	Task Units	Task Cost
Laborer	hrs	$17.16	2,100	$36,030
Cat D8N Dozer With Ripper	hrs	$103.84	375	$38,938
Cat D8N Dozer Operator	hrs	$26.00	375	$9,750
Cat 980 Loader	hrs	$100.39	2,100	$210,823
Cat 980 Loader Operator	hrs	$26.00	2,100	$54,600
Screening Plant w/conveyors*	hrs	$72.46	2,100	$152,164
BLM Usage Fee	CY	$0.60	214,500	$128,700
Contract Highway Trucks - Bellydumps**	hrs	$100.50	5,571	$559,929
Equipment Maintenance (Butler)	hrs	$22.45	2,475	$55,576
Total Production of RipRap				**$1,246,509**
RIPRAP COST PER CUBIC YARD DELIVERED				**$6.60**

* Cost Quoted from Power Motive Corporation, Denver, Colorado updated February 14, 2012
$12,800 (less 10%) for screen and conveyors, 176 hours per month for one month, plus screen set up at $2,500.
Mob and Demob - $ 5,500.00
Rental costs for screening equipment increased by CPI-U 2012, 2013, 2014 and 2015 of 1.74%, 1.50%, 0.80% and 0.50% respectively.

** Cost quoted from Dennis Cosby, Cosby Trucking, Inc., Blanding, Utah, Updated 3/3/14. Escalated by 2015 CPI of 0.5%.
(includes ownership expense, fuel, maintenance and operator)

Long Term Care

LONG TERM CARE CALCULATION
March 2016

Base Amount (Starting in Dec. 1978)	$250,000
CPI-U December, 1978	67.7
CPI-U November 2015	237.336

ATTACHMENT D

RADIATION PROTECTION MANUAL FOR RECLAMATION ACTIVITIES

Responsible Authority

Radiation Safety Officer

The Radiation Safety Officer (RSO) shall meet the requirements as specified in section 2.4, Technical Qualifications of Health Physics Staff in NRC Regulatory Guide 8.31. Along with meeting the requirements outline in Regulatory Guide 8.31, the RSO must also be submitted and approved by the State of Utah as an acceptable responsible authority for reclamation activities.

The RSO will be responsible for following and complying with all rules and specifications that are outlined in the Reclamation Plan along with all standards pertaining to the health and safety of the employees and environment. The RSO must also maintain accurate documentation of all decontamination and disposal activities. The RSO will have the responsibility of overseeing all aspects of this procedure and all total releases of any materials from the facility. These records will be maintained on site for review.

1.0 RADIATION MONITORING – PERSONNEL

This section contains the following procedures for personnel radiation monitoring including: (1) airborne particulates (2) alpha surveys (3) beta/gamma surveys and (4) urinalysis surveys.

1.1 AIRBORNE PARTICULATES

Sampling for personnel exposure to airborne particulate radionuclides, other than for radon progeny, will be done utilizing two distinct sampling protocols: (1) personnel breathing zone samplers, and (2) ambient air high volume samplers. Specific standard operating procedures for these two collection methods are described in Section 1.1.2 and 1.1.3 below.

1.1.1 Frequency

For work where there is the potential to cause airborne radiation doses to site personnel, the frequency and type of air sampling to be conducted is determined from measured air concentrations:

0.01 DAC – 0.1 DAC	Quarterly or monthly area air sampling and/or bioassay measurements
> 0.1 DAC	Continuous sampling is appropriate if concentrations are likely to exceed 0.10 DAC averaged over 40 hours or longer.

The RSO will determine the exact frequency of area air sampling, breathing zone sampling and/or bioassay measurements and determine how many workers in a group of workers performing similar jobs are to be equipped with breathing zone air samplers. Higher airborne concentrations warrant more frequent use of area air samplers, bioassay measurements, and breathing zone air samplers. Area air samplers may be used where documentation exists showing the sample is equivalent to a breathing zone sample. Breathing zone samples taken within one foot of the worker's head are considered representative without further documentation. Breathing zone air samplers are preferred under work conditions of higher airborne concentrations. Table 1.1.1-1 below, from Regulatory Guide 8.25, provides additional guidance for the RSO in designing and implementing air sampling programs for specific jobs.

Table 1.1.1-1
Air Sampling Recommendations Based on Estimated Intakes and Airborne Concentrations

Worker's Estimated Annual Intake as a Fraction of ALI	Estimated Airborne Concentrations as a Fraction of DAC	Air Sampling Recommendations
< 0.1	< 0.01	Air sampling is generally not necessary. However, monthly or quarterly grab samples or some other measurement may be appropriate to confirm that airborne levels are indeed low.
	> 0.01	Some air sampling is appropriate. Intermittent or grab samples are appropriate near the lower end of the range. Continuous sampling is appropriate if concentrations are likely to exceed 0.1 DAC averaged over 40 hours or longer.
> 0.1	< 0.3	Monitoring of intake by air sampling or bioassay is required by 10 CFR 20.1502(b).
	> 0.3	A demonstration that the air samples are representative of the breathing zone is appropriate if (1) intakes of record will be based on air sampling and (2) concentrations are likely to exceed 0.3 DAC averaged over 40 hours (i.e., intake more than 12 DAC-hours in a week).
Any annual intake	> 1	Air samples should be analyzed before work resumes the next day when potential intakes may exceed 40 DAC-hours in 1 week. When work is done in shifts, results should be available before the next shift ends. (Credit may be taken for protection factors if a respiratory protection program is in place.)
	> 5	Continuous air monitoring should be provided if there is a potential for intakes to exceed 40 DAC-hours in 1 day. (Credit may be taken for protection factors if a respiratory protection program is in place.)

1.1.2 Breathing Zone Sampling

1.1.2.1 General

Breathing zone samplers (SKC pumps and accessory kits, or equivalent) are used to determine airborne exposure to uranium while individuals are performing specific jobs. The units consist of a portable low volume pump that attaches to the individuals belt, tygon tubing and filter holder that is attached to the individual's lapel or shirt collar. The unit monitors airborne uranium in a person's breathing zone. Pumps must be recharged after 6 to 8 hours of use.

1.1.2.2 Applicability

Breathing zone samples are required:

- for all calciner activities,
- at least quarterly during routine tasks on representative individuals performing these tasks,
- when radiation work permits are issued in which airborne concentrations may exceed 25% of 10 CFR Part 20 limits, or
- at the discretion of the RSO.

1.1.2.3 Procedure

The procedure for collecting a breathing zone sample is as follows:

1. Secure the breathing zone sampler, which has been charged and loaded with a filter paper from the radiation department.

2. Secure the pump to the worker's belt and the filter holder to the shirt collar or lapel. Try to secure pump tubing to minimize restriction of motion.

3. Turn pump on (record the time pump was turned on) and continue monitoring until the work being monitored is completed and the worker no longer is in the exposure area. Record the time at which the job is complete.

4. Return the pump and accessories to the RSO, who will remove the filter paper for analysis. Be sure to indicate accurately the total time taken by the work being monitored.

5. Analysis of filter samples will be performed using a sensitive alpha detector. The procedure is as follows: (a) count a background sample for ten minutes; (b) divide the background count by ten to obtain the background count rate in cpm; (c) Place the breathing zone sample in the instrument and count the sample again for ten minutes;

(d) divide the sample count by ten to obtain the count rate in cpm; (e) subtract the background count rate from the sample count rate; and, (f) record all data on the Breathing Zone sampling analysis form (a copy of which is attached).

6. Record the total hours of exposure that are being assigned to the employee on the Employee Exposure form, which is maintained in personnel folders. Be sure to consider protection factors permitted by respirator use if the employee was also wearing respiratory protection during the job.

7. The number of DAC hours assigned is calculated using the following formula:

$$\text{DAC hours of exposure} = \frac{\text{Measured air concentration}}{(\text{DAC})(\text{PF})} \times \text{Total hours of exposure}$$

where: DAC = Derived Air Concentration (for uranium; 10 CFR Part 20, Appendix B)

PF = protection factor for respirator use. If no respiratory protection was used PF =1.

The measured air concentration must be in μCi/cc.

1.1.2.4 Calibration

Prior to use, calibration of the breathing zone samplers will be done using a calibration method as described in Section 3.2.

1.1.2.5 Equipment – Breathing Zone Sampler

The equipment used for breathing zone samples consists of:

1. Personal sampling pumps
2. Gelman 37 mm Delrin filter holders, or equivalent
3. Gelman 37 mm type A/E glass fiber filters, or equivalent
4. Kurz Model 543 air mass flow meter, or equivalent

1.1.2.6 Data Record

Data maintained on file includes:

1. Time on and off for each sample pump.
2. Sampling location(s).
3. Individual's name, identification number, etc.
4. Date and sample number.

5. Sample count rate.

1.1.2.7 Calculations

The airborne concentration in μCi/cc is equal to the sample count rate minus the background count rate in cpm divided by the instrument alpha efficiency, the sample flow rate in cc/minute, the sample time in minutes and a conversion factor converting dpm to μCi.

The calculation is:

Equation Number 1:

$$\text{Airborne concentration} = \frac{\text{(Count Rate)}}{\text{(Time)(eff)(Conversion factor)(Flow Rate)}}$$

$$\text{i.e. } \frac{\text{uCi}}{\text{cc}} = \frac{\text{(cpm-Bkg) 1 uCi} \quad (1) \quad (1)}{(\text{eff})(2.22\text{x}10^6\text{dpm})(\text{cc/min})(\text{min})}$$

where: eff = cpm/dpm for counting instruments
cpm = counts/min
dpm = disintegrations/min
Conversion factor 1 μCi = $2.22\text{x}10^6$ dpm
Flow Rate = cc/min
Collection time = min

Once the airborne concentration has been calculated it is possible to calculate personnel exposure in microcuries (μCi). Personnel exposure is determined for an individual who is working in an area at a known air concentration (μCi /cc) for a given amount of time (hours) breathing the area air at an assumed rate. The breathing rate for a standard person (Handbook of Radiological Health) is 1.20 cubic meters per hour (m^3/hr).

The calculation for personnel exposure is:

Equation Number 2:

Exposure μCi = (μCi /cc)(1.20m^3/hr)(hours of exposure)(conversion rate)

Where: μCi /cc = air concentration from Equation 1

1.20 m^3/hr = breathing rate for standard man (ICRP)
hours of exposure = hours
conversion factor = 10^6cc/m^3

It is also possible to determine the percent or fraction of the Derived Air Concentration (DAC) for a particular radionuclide using the information obtained from the exposure calculation and dividing this value by the regulatory limit DAC listed in 10 CFR Part 20.

% DAC = Exposure in μCi / μCi limit 10 CFR Part 20

For the natural uranium (U-Nat) the DAC limits from 10 CFR Part 20 for insoluble Class Y compounds are as follows:

- Weekly 1.0 x 10^{-3} μCi /week
- Quarterly 1.25 x 10^{-2} μCi /Qt
- Yearly 5.0 x 10^{-2} μCi /yr

1.1.2.8 ALARA/Quality Control

The RSO reviews each monitored result and initiates action if levels exceed 25% of 10 CFR 20 limits. At a minimum, ten percent (10%) of the air samples collected in a given quarter will be recounted using the same instrument or using a different instrument and these results will be compared to the original sample results. Deviations exceeding 30% of the original sample results will be reviewed by the RSO and the samples will be recounted again until the sample results are determined to be consistent. Additional QA samples consisting of spiked air samples, duplicate samples and blank samples will be submitted to the radiation department for counting. This will be based on ten percent (10%) of the number of samples collected during a quarter. The sample results will be compared to the spiked values, duplicate values, or blank (background) values of the prepared sample. Deviations exceeding 30% of the determined spiked, duplicate or blank value will be recounted. If no resolution of the deviation exceeding 30% is made the QA samples preparation will be repeated. Periodic reviews by the RSO and the ALARA audit committee will be made and documented to ensure quality maintenance and ALARA control.

1.1.3 Airborne High Volume Sampling

Grab air sampling involves passing a representative sample of air through a filter paper disc via an air pump for the purpose of determining the concentration of uranium in breathing air at that location. Although the process is only measuring airborne concentrations at a specific place and at a specific time, the results can often be used to represent average concentration in a general area. A high volume sample pump will be used for this purpose. Samples will be analyzed as per standard gross alpha analysis procedures using a sensitive alpha detector.

1.1.3.1 Frequency and Locations

The following principles used for the collection of area grab samples must be considered when collecting a sample in order to obtain a representative air concentration that workers may be exposed to during their assigned work tasks.

1. The locations selected for sampling should be representative of exposures to employees working in the area.
2. For special air sampling, the sampling period should represent the conditions during the entire period of exposure. This may involve sampling during the entire exposure period.
3. For routine sampling, the sampling period must be sufficient to ensure a minimum flow rate of 40 liters per minute (lpm) for at least 60 minutes.
4. Sample filters will be analyzed for gross alpha using a sensitive alpha detector.
5. Grab sampling procedures may be supplemented by use of Breathing Zone Samples for special jobs or non-routine situations.

1.1.3.2 Sampling Equipment

Monitoring equipment will be capable of obtaining an air sample flow rate of at least 40 liters per minute for one hour or longer. Equipment utilized will be and Eberline RAS-1, or a Scientific Industries Model H25004, or equivalent. Filter media will be of appropriate micron pore diameter. Equipment is calibrated prior to each usage as per Section 3.3 of this manual.

1.1.3.3 Sampling Procedure

Steps for collection of area airborne grab samples are as follows:

1. A high volume pump will be used for sample collection.
2. Check sample pump calibration.
3. Locate sampler at designated site. Insert a clean filter, using tweezers, into the filter holder on the sampler. Do not contaminate the filter. Log start time and conditions at the site.
4. Collect a sample for a minimum of 60 minutes at a flow rate of 40 lpm.
5. After sampling is completed, carefully remove the filter, using tweezers, from the filter holder and place it in a clean envelope, or in the plastic casing furnished with the filter.

6. Log all sample data on the log sheet.
   A. Sample location and number (also on the envelope).
   B. Time on, time off and date.
   C. Mill operating conditions at the site.
   D. Sampler's initials.

7. Analyze for gross alpha

1.1.3.4 Calculations

Perform calculations as described in Section 1.1.2.7.

1.1.3.5 Records

Logs of all samples taken are filed in the RSO's files. Data are used to calculate radiation exposures as described in Section 4.0.

Whenever grab sampling results indicate that concentrations in work locations exceed 25% of the applicable value in 10 CFR Part 20, Appendix B, time weighted exposures of employees who have worked at these locations shall be computed. Calculations will reveal an individual's exposure in DAC hours. This value shall be assigned to the worker and logged onto the worker's "Employee Exposure to Airborne Radionuclides" form. This form is in Section 4. Whenever special air sampling programs (as required for cleanup, maintenance, decontamination incidents, etc.) reveal that an employee has been exposed to airborne radioactive material, the calculated value shall also be entered on the individual's exposure form.

1.1.3.6 Quality Assurance

Calibration checks on each air sampler, prior to field use, ensure accurate airflow volumes. Use of tweezers and new filter storage containers minimizes contamination potential. Field logging of data during sampling and logging of identifying data on sampled filter containers minimizes sample transposition. Quality control samples will be analyzed as described in Section 1.1.2.8

Review of data by the RSO and by the ALARA Audit committee further assures quality maintenance.

1.2 ALPHA SURVEYS

1.2.1 Restricted Area

The Restricted Area is defined as:

1. The property area within the chain link fence surrounding the mill property and the area enclosed to the north and east of the facility by the posted Restricted Area fence.

2. The active tailings and liquid waste disposal areas.

All personnel who enter the Restricted Area will monitor themselves each time they leave the Restricted Area and at the end of their shift. The Radiation Safety Department will review the monitoring information. All personnel exiting the Restricted Area must initial a record of their monitoring activity.

1.2.2 Instrumentation

The instrumentation utilized for personnel alpha scanning is listed in Appendix 1 at the end of this manual. Personnel alpha survey instruments are located at the exits from the Restricted Area.

1.2.3 Monitoring Procedures

The monitoring procedure includes the following steps:

1. The alarm rate meter is adjusted within the range of 750 to 1,000 dpm/100 cm^2 to ensure a margin of 250 dpm/100 cm^2 due to the low efficiency of this instrumentation.

2. An individual monitors himself by slowly passing the detector over their hands, clothing and shoes, including the shoe bottoms, at a distance from the surface of approximately ¼ inch. An area that is suspected of possessing any contamination (i.e. hands, boots, visible spotting/stain on clothing etc.) should be carefully monitored by placing the detector directly on the surface and note the measurement.

3. Should an alarm be set off indicating the presence of contamination, the individual should:
    a. Resurvey themselves to verify the contamination.
    b. If contamination is present the individual must wash the affected area and again resurvey themselves to ensure the contamination has been removed.

4. If the decontamination efforts by the individual are not successful, then the Radiation Safety personnel will be contacted to assess the situation. Further decontamination may be required.

5. If an individual's clothing cannot be successfully decontaminated, they must obtain clothing from the warehouse to use and must launder the personal clothing in the laundry room.

6. Individual surveys are to be logged and initialed.

7. Access to and from the Mill's Restricted Area by all Mill workers, contractors and delivery personnel, other than Radiation, Safety and Environmental Staff, Senior Laboratory personnel, Mill Management and Mill Supervisory personnel and others as may be designated by the RSO, will be limited to one or more access points as may be designated by the RSO from time to time.

8. A Radiation Technician will be positioned at each access point designated by the RSO under paragraph 7 above during peak transition times, such as during breaks and at the ends of shifts, to observe that each worker, contractor or delivery person is performing a proper scan.

1.2.4 Training

All employees will be trained on the proper scanning procedures and techniques.

1.2.5 Records

Log sheets will be collected daily and filed by the Radiation staff. Records will be retained at the Mill. Contamination incidents will result in a written record, which is maintained on file.

1.2.6 Limits/ALARA

Contamination limits for personnel scans are set at 1,000 dpm/100 cm^2. Records will be reviewed by the RSO to maintain levels noted as low as reasonable achievable.

1.2.7 Quality Assurance

A random check of an individual's scanning technique provides quality assurance of the monitoring procedures. Daily function checks using calibrated sources assures instrumentation performance. Periodic review by the RSO and the ALARA audit committee document and ensure quality control and ALARA maintenance.

1.3 PERSONNEL BETA-GAMMA MONITORING

Site employees working within the Restricted Area will be required to wear a personal monitoring device (such as a TLD, LUXEL badge or other NVLAP approved device which has been approved by the RSO and the SERP) during their work period. The personal monitoring devices are normally issued to each employee quarterly; however, during pregnancy or if the radiological potential for exposure to an individual is anticipated to be elevated and requires quick assessment the badges may be issued monthly.

1.3.1 Monitoring Procedures

The monitoring procedures consist of:

1. Personnel issued personal monitoring devices will wear the device on the trunk (torso) of the body. The personal monitoring device records beta/gamma radiation as well as other forms of penetrating radiation such as x-rays. A personal monitoring device is an exposure record of an individual's personal exposure to radiation while on the job. Therefore, personal monitoring devices are to remain at the Mill and stored on the assigned dosimeter storage boards. All exposure records obtained by a personal monitoring device which are not consistent with the exposure rates of work tasks or work location measurements made throughout the Mill will be evaluated by the RSO. This evaluation will result in an investigation by the RSO and a written explanation of the findings. These written records will be maintained at the Mill.

2. Personal monitoring devices will be issued at a minimum quarterly and will be exchanged by the Radiation Safety Department. Missing or lost badges will be reported to management.

3. Female employees that become pregnant and continue to work during the course of their pregnancy will be placed on a monthly personal monitoring device exchange during this period. NRC Regulation Guide 8.13 provides guidelines to be followed during pregnancy and is made part of this procedure.

1.3.2 Records

The Radiation Safety Department will maintain all occupational exposure records in the departmental files:

1. Occupational exposure records are a part of an individual's health record and, as such, will be considered private information.

2. An individual may examine his/her exposure record upon request.

3. An employee terminating his/her employment with the Company may request a copy of his/her occupational exposure records.

4. The Radiation Safety Department on the signature of the employee will request prior occupational exposure records.

5. Occupational exposure records will be made available to authorized company or regulatory personnel.

1.3.3 Quality Assurance

Periodic reviews by the RSO and the ALARA audit committee document and ensure quality control and maintenance of conditions ALARA.

1.4 URINALYSIS SURVEYS

1.4.1 Frequency

Urinalyses will be performed on those employees that are a) exposed to potential airborne yellowcake or involved in maintenance tasks during which yellowcake dust may be produced, or b) routinely exposed to airborne uranium dust. Baseline urinalyses will be performed prior to initial work assignments.

Urine samples are collected on a routine basis from employees as required in Regulatory Guide 8.22. Samples will be collected from all employees monthly. Bi-weekly samples will be collected if individual exposures are expected to exceed 25% of the DAC value. Non-routine urinalyses will usually be performed on employees who have been working on assignments that require a Radiation Work Permit, and always on any individual that may have been exposed to airborne uranium or ore dust concentrations that exceed the 25% of the DAC level.

1.4.2 Specimen Collection

Clean, disposable sample cups with lids will be provided to each employee that will be required to submit a urine specimen. The containers will be picked up at the administration building before the individual enters the Restricted Area.

The container, filled with specimen, will be returned to the bioassay laboratory prior to reporting to work. The name of the employee and the date of collection will be indicated on the specimen cup.

A valid sample must be collected at least 40 hours, but not more than 96 hours, after the most recent occupancy of the employee's work area (after two days, but not more than four days off).

The specimen should be collected prior to reporting to the individual's work location. To prevent contamination, the hands should be carefully washed prior to voiding.

Under unusual circumstances where specimens cannot be collected in this manner, the worker will shower immediately prior to voiding.

1.4.3 Sample Preparation

Equipment required:

- 15 ml disposable centrifuge tubes with lids
- 10 ml pipette
- 1 mL pipette
- 200 µL pipette
- 5 µl pipette
- 10 µl pipette
- Disposable tips for the above pipettes
- 1,000 ppm uranium solution
- Spiking solution – 0.03 or 0.02 g/l of uranium in de-ionized water

After the specimens are received, they will be stored in a refrigerator until they are prepared for analysis.

Sample preparation will be done in an area decontaminated to less than 25 dpm alpha (removable) per 100 cm^2 prior to preparation of samples. All of the equipment that is used in sample preparation will be clean and maintained in such condition.

A log will be prepared and the following information will be kept for each urinalysis performed:

Sample identification number
Name of employee submitting the specimen
Date of sample collection
Date the sample was sent to the laboratory
Date the results were received
Results of the urinalysis in µg/1
Indication of any spike used in µg/1

The centrifuge tubes will be marked with a sample identification number. 10 milliliters of urine will then be pipetted into the centrifuge tube using the pipette device. Or 1 milliliters of urine will then be pipette into the centrifuge tube using the pipette device (To prevent contamination, a new tip must be used for each specimen.) After each step of the procedure, the proper entry must be made in the logbook.

The samples that are to be spiked for quality assurance purposes will then be prepared. The spikes will be introduced into the sample with 5 µl or 10 µl pipettes. A new tip must be used with each spike. With the standard spike solution (0.03 g/l of U), a 5 µl spike will result in a 15 µg/l concentration for the 10 ml sample; the 10 µl spike will give 30 µg/l). The proper entry must be made in the logbook for each sample spiked.

After preparation has been completed, the QA samples are securely packaged as soon as practicable and sent to the contract laboratory for analysis.

The samples that are to be analyzed in-house will be placed in the chemistry laboratory's refrigerator until the analysis can be completed. A copy of the in-house analytical procedure is described in Section 1.4.7.6. Once the on-site laboratory is no longer functional, all samples will be submitted to a certified laboratory.

1.4.4 Quality Assurance

To assure reliability and reproducibility of results, at least 25% of the samples that are submitted for analysis will be used for quality assurance purposes. These samples will consist of spikes, duplicates, and blanks (samples collected from individuals known to have no lung or systemic uranium burden).

Spiked samples will be prepared as stated under sample preparation of this procedure.

Duplicates will be identical samples of the same specimen and/or spikes of identical concentrations.

To assure reliability of the in-house analytical procedure, 10% of the samples will be sent to a contractor laboratory for analysis. These samples will contain quality assurance items designed to provide intra-laboratory comparisons.

1.4.5 Analysis

After the samples are collected as outlined in Guide 8.22, they are identified to the lab by collection date and number. Urinalysis results must be completed and reported to the Radiation Safety Department within seven days of the sample collection.

1.4.5.1 Equipment List

1. Specimen collection cups with disposable lids (VWR No. 15708-711 or equivalent)
2. Screw cap, disposable, graduated 15 ml centrifuge tubes (Corning No. 25310 or equivalent)
3. Micro-pipettes 1 each 5, 5 each 10 µL (Oxford Model 7000 or equivalent)
4. Adjustable Finnpipette each 1,000 µL, 200 µL and 5 mL
5. Disposable micro-pipette tips for micro-pipettes (Oxford No. 910A or equivalent)
6. Fume Hood
7. Ultrasonic Cleaner
8. PE-SCIEX ELAN DRC II AXIAL FIELD TECHNOLOGY ICP-MS (or equivalent)
9. Polyscience Water Circulator (or equivalent)
10. Perkin-Elmer AS-10 Auto Sampler (or equivalent)

11. Thermo Scientific Vortex mixtures (or equivalent)

1.4.5.2 Reagent List

1. 1% to 2% Nitric Acid
2. Concentrated Nitric Acid
3. 1,000 µg/ml Uranium Stock Solution, certified vendor prepared
4. Dilutions of the above stock solution, replaced bi-annually. Used for QA/QC.
5. Appropriate Cleaning Solution for Ultrasonic Cleaner
6. 1,000 µg/ml Uranium Stock Solution, purchased from certified vendor to use as calibration standard at different dilutions

Ensure that all reagents used are within their expiration dates listed on each reagent package, if applicable.

1.4.5.3 Premise

A portion of urine is diluted with 2% Nitric acid solution, mixed thoroughly and analyzed.

1.4.5.4 Safety Precautions

1 Follow laboratory guidelines when working with acids.

2. Utilize all appropriate PPE.

1.4.5.5 Sample Preparation Procedure

1. Compare sample numbering with bioassay result sheet to insure order and eliminate discrepancies.

2. To 15 ml centrifuge tube add 1 mL urine sample, 200 µL internal standard of 1,000 ppb and 2% Nitric acid to make up volume to 10 mL.

3. Maintaining sample order of left to right, front to back, lowest sample number to highest sample number in the set.

4. Use vortex to mix it thoroughly.

5. Analyze using procedure on the ICP-MS described in section 1.4.5.6.

1.4.5.6 ICP-MS Procedures

Special considerations: Because of the high salt content of the samples, it is necessary to clean the skimmer and sampler cones after each use.

1. Turn the argon on at the tank and set the delivery pressure at 80 pounds per square inch (psi).

2. Turn on the exhaust fan and the water supply to the ICP-MS. The water supply has to have a delivery pressure of 70 psi. It may be necessary to change the filters on the water supply in order to achieve sufficient water supply pressure. The ICP-MS will not operate below this pressure.

3. Turn on the computer, monitor and printer.

4. On the windows desktop, double-click the ELAN icon.

5. Check the condition of the sample introduction system.

6. Check that the sample tubing and drain tubing leading from the peristaltic pump to the spray chamber are properly set up and in good working condition. It is recommended to use new tubes every day.

7. Place the capillary tubing into a container of 2% Nitric acid solution.

8. Open the instrument window, and then click the Front Panel Tab.

9. On the front panel tab click vacuum start.

10. When the instrument is ready, click Plasma Start.

11. After the plasma ignites, allow the instrument to warm up for 45 minutes.

12. To begin sample analysis, click the sample tab, build the sample analysis list and click on analyze sample.

13. After the last sample, aspirate the blank long enough to clean the lines.

14. Allow the pump to run long enough without aqueous uptake to void all lines.

15. Turn the flame off and relax lines off of pump.

16. After 5 to 10 minutes, turn off the water supply, exhaust fan and argon.

All bioassay samples need to be analyzed three (3) working days from receipt in the laboratory. Samples are extremely susceptible to contamination. Precautions should be taken to minimize traffic and fugitive dust while samples are digesting.

1.4.6 Reporting and Corrective Actions

As soon as the analytical results are received, they are entered in the logbook and the entries are checked for correctness and completeness.

The lab report is returned to the Radiation Safety Department with results reported as micrograms/liter of uranium. The information must be placed in the individual employee's exposure file and maintained as directed by the DRC.

The Radiation Safety Department is notified immediately of any sample with a concentration greater than 35 micrograms/liter of uranium. Corrective actions will be taken when the urinary uranium concentration falls within the limits listed in Table 1 (attached).

The Radiation Safety Department should compute the error on the control spiked samples and advise the lab if the results are more than ± 30% of the known values. If any of the results obtained for the quality assurance control samples are in error by a ± 30%, the analysis must be repeated.

1.5 IN-VIVO MONITORING

In-vivo body counting for lung burdens of U-natural and U-235 will not be routinely conducted. Monitoring will be conducted at the discretion of the RSO, samples may be sent for a follow-up analysis for specific radionuclides in consultation with DUSA management should potential exposure to an individual warrant.

2.0 RADIATION MONITORING – AREA

2.1 HIGH VOLUME AIRBORNE AREA AIR SAMPLING

Area air sampling involves passing a representative sample of air through a filter paper disc via an air pump for the purpose of determining the concentration of uranium in breathing air at that location. Although the process is only measuring airborne concentrations at a specific place and at a specific time, the results can often be used to represent average concentration in a general area. A high volume sampler or similar high volume pump will be used for this purpose. Samples will be analyzed as per standard gross alpha analysis procedures using a sensitive alpha detector.

2.1.1 Equipment

Monitoring equipment will be capable of obtaining an air sample flow rate of 40 lpm or greater for one hour or longer. A variety of equipment may be used for area air sampling, however normally the equipment used is an Eberline RAS-1, Scientific Industries Model H25004, or equivalent. Equipment is calibrated prior to each usage as per Section 3.6 of this manual.

2.1.2 Frequency/Locations

Area dust monitoring frequency is monthly for the locations shown in Table 2.1.2-1.

Table 2.1.2-1
Airborne Radiation Sample Locations

Code	Location/Description
BA1	Ore Scalehouse
BA2	Ore Storage
BA6	Sample Plant
BA7	SAG Mill Area
BA7A	SAG Mill Control Room
BA8	Leach Tank Area
BA9	Washing Circuit CCD Thickness
BA10	Solvent Extraction Building/Stripping Section
BA11	Solvent Extraction Building/Control Room
BA12	Yellowcake Precipitation & West Storage Area
BA12A	North Yellowcake Dryer Enclosure
BA12B	South Yellowcake Dryer Enclosure
BA13	Yellowcake Drying & Packaging Area
BA13A	Yellowcake Packaging Enclosure
BA14	Packaged Yellowcake Storage Room
BA15	Metallurgical Laboratory Sample Preparation Room

Code	Location/Description
BA16	Lunch Room Area (New Training Room)
BA17	Change Room
BA18	Administrative Building
BA19	Warehouse
BA20	Maintenance Shop
BA21	Boiler
BA22	Vanadium Panel
BA22A	Vanadium Dryer
BA23	Filter Belt/Rotary Dryer
BA24	Tails
BA25	Central Control Room
BA26	Shifter's Office
BA27	Operator's Lunch Room
BA29	Filter Press
BA30	Truck Shop
BA31	Women's Locker Room
BA32	Oxidation
BA33A	AF South Pad
BA33B	AF North Pad

Areas BA-10 and BA-12 were soluble uranium exposure areas. These areas were areas where the uranium compounds that were produced are soluble in lung fluids and are comparatively quickly eliminated from the body. All the other areas are insoluble exposure areas. Insoluble uranium areas were areas where the uranium compounds are not readily soluble in lung fluids and are retained by the body to a higher degree. Temperature of drying operations has a significant impact on solubility of uranium compounds. High drying temperatures produce insoluble uranium compounds. Area uranium dust monitoring, during production periods, is weekly in the designated yellowcake production areas. Monitoring increases to weekly in other monitored areas with the observance of levels exceeding 25% of 10 CFR 20 limits and reverts to monthly upon a continued observance of levels below 25% of 10 CFR 20 limits as determined by the RSO. The RSO may also perform any additional samplings at his or her discretion.

As areas are decommission and the ability to sample those areas is removed, the RSO will document this in the files and those areas will be removed from further monitoring.

2.1.3 Sampling Procedures

1. A RAS-1 or similar high volume pump shall be used for area grab sampling. Insure the pump has been recently calibrated within the past month.

2. The locations selected for area air samples should be representative of exposures to employees working in the area.

3. For routine sampling, the sampling period should be for a minimum collection duration of 60 minutes at a flow of 40 lpm or greater.

4. Insert a clean filter into the filter holder on the sampler. Note start time of pump and record unusual mill operating conditions if they exist.

   A. Stop sample collection and note time. Normally, an automatic timer is connected to the sampler and a 1 hour sample collection time is used.

6. Remove the filter from the sampler and place in a clean glassine envelope or the package supplied by the manufacturer for delivery to the Radiation Department.

7. Count the sample by gross alpha counting techniques and enter the result and sampling information into the record.

2.1.4 Calculations

Perform calculations as specified in Section 4.0.

2.1.5 Records

Logs of all samples taken are filed in the Radiation Safety Officer's files. Data is utilized to calculate radiation exposures as specified in Section 4.0.

2.1.6 Quality Assurance

Calibration checks on each air sampler are made at least monthly to ensure accurate airflow volumes are being collected. Usage of tweezers and new filter storage containers minimizes contamination potential. Field logging of data during sampling and logging of identifying data on sampled filter containers minimizes sample transposition. Samples may periodically be submitted for chemical analysis and a comparison of these results to the radiometric measurements will be made.

Review of data by the RSO and by the ALARA audit committee further assures quality maintenance.

2.2 RADON PROGENY

2.2.1 Definitions

Working Level:

A. The exposure to 1.3E + 05 MEV of alpha energy or the potential alpha energy in one liter of standard air containing 100 pCi each of RaA (Polonium-218), RaB (Lead-214), RaC (Bismuth-214), and RaC prime (Polonium-214). (Exposure level, not a dose rate)

Kusnetz Method: Method of radon progeny measurement and calculation based upon a 10 liter sample and at least 40 minutes decay time before counting.

2.2.2 Equipment

The equipment utilized consists of the following, or appropriate equivalents:

- Portable personal sampler
- Gelman 25 mm filter holder with end cap, or equivalent
- Gelman Type A/E 25 mm diameter glass fiber filters, or equivalent
- Counter-Scaler – Eberline MS-3 with SPA-1 probe, or equivalent

2.2.3 Frequency/Location

Radon progeny samples are obtained monthly for only those locations occupied by personnel where exposures may have the potential of exceeding 25% of 10 CFR 20 limits.

2.2.4 Procedures

The procedures to be utilized are as follows:

1. Assemble filter trains.

2. Ensure pump batteries are fully charged.

3. Calibrate pump (see Section 3.5).

4. Attached filter trains at sample locations; disconnect end plug.

5. Collect sample in the breathing zone of the employee.

6. Collect sample for five minutes at 4.0 lpm.

7. Log sample site, time started, time stopped, and filter pump number prior to leaving each site on the field log notebook.

8. Samples are counted between 40 minutes and 90 minutes after collection using sensitive alpha detector.

9. Check the calibration and function check information to ensure the detector is calibrated and operating.

10. If the calibration check correlates, proceed with sample analysis.

11. Radon progeny samples are normally counted for three minutes; however any sample count time may be selected for counting.

12. Run background detector count prior to running sampled filters.

13. After counting, calculate working levels.

Equation:

$$\frac{(\text{CPM - Bkg})}{(\alpha \text{ eff})\ (20 \text{ liters})\ (\text{Time Factor})} = \text{WL}$$

Where:

CPM - sample count per minute
Bkg - counter-detector background count per minute
α Efficiency - The efficiency of the counting system (See Section 3.2.3.3)
Time Factor - Values determined from Kusnetz method (See attached Table 2.2.4-1)
WL - Working Levels

TABLE 2.2.4-1
Time Factors

Min.	Factor	Min.	Factor
40	150	71	89
41	148	72	87
42	146	73	85
43	144	74	84
44	142	75	83
45	140	76	82
46	138	77	81
47	136	78	78
48	134	79	76
49	132	80	75
50	130	81	74

68	94		
69	92		
70	90		

2.2.5 Exposure Calculations

The personnel exposure calculations are a job-weighted average of those areas and concentrations that an individual is exposed to. The procedure is:

1. Determine areas and durations (hrs.) each individual worked during the period (month and quarter).

2. Determine monitored concentrations (WL) for each area so noted.

3. The multiplication of the hours worked in each area by the area concentration (WL) noted is added to the result for each area involved in the period.

4. The result is the Working Level Hours exposed (WLH) for the period.

5. The working level hours (WLH) divided by 173 (30 CFR 57.5-40 note); or hours per month gives the working level months (WLM) exposure. (The limit is 4 working level months exposure per year.)

6. If calculated per quarter, the working level hours summed for the quarter are divided by 519 (173 X 3) to obtain the working level quarter exposure.

See Section 4.0 for details on how to perform exposure calculations and maintain the exposure records.

2.2.6 Records

Data records, which are filed in the Radiation Safety files, include:

1. Sample location
2. Date and time of sample
3. Time on and off of sample pump
4. Counts per minute of sample
5. Elapsed time after sampling
6. Background detector count
7. Appropriate Kusnetz time factor
8. Working level
9. Sampler identification

Employee exposure records include:

1. Month monitored
2. Areas and duration worked
3. Employee identification
4. Concentrations (WL) observed
5. Calculated WLMs

2.2.7 Quality Assurance

Calibration checks each month assure proper calibration of the counting equipment. Documented semi-annual calibrations of the counting equipment using certified alpha calibration and pulse meter sources ensure proper calibration of the equipment over the anticipated ranges. The air sampling system has documented calibration prior to each use, ensuring sampling the appropriate air volumes. Duplicate counts of select data may be counted to assure instrument precision. Field documentation is maintained for each sample during monitoring. This methodology provides assurance in data quality.

Review of data by the RSO and the ALARA audit committee further assures quality maintenance.

2.3 ALPHA SURVEYS

2.3.1 Equipment

Equipment to be utilized in area alpha surveys is shown in Appendix 1. Pre-use function checks will be performed on all radiation survey equipment as specified in Section 3.1.2.3.2.

2.3.2 Frequency/Locations

Fixed and removable alpha surveys are made at those general locations on the Table 2.3.2-1, "Alpha Area Survey Locations." Surveys are completed weekly in those areas designated by the RSO as authorized lunchroom/break areas are monitored. Designated eating areas are listed in Table 2.3.2-2.

As areas are decommission and the ability to sample those areas is removed, the RSO will document this in the files and those areas will be removed from further monitoring.

2.3.3 Procedures

2.3.3.1 *Respirators*

Respirators are monitored utilizing a removable alpha smear that is read using alpha scaler meter such as a Ludlum Model 2200 or other equivalent radiological instruments. Readings exceeding 100 dpm/100 cm^2 result in re-cleaning or discarding of the respirator. Respirator cleaning and monitoring is a function of the Radiation Safety staff assigned to this duty. The meter's performance is checked prior to each use period.

2.3.3.2 *Fixed Alpha Surveys*

Alpha surveys for fixed alpha contamination are performed using a variety of alpha detecting instruments, as listed in Appendix 1. Each instrument is checked using a calibrated alpha source for proper function and operation prior to use, as described in Section 3.1.2.3.2.

Adjustments to the surface area being measured must be made to convert from the particular detector's surface area to the commonly used surface area of 100 cm^2. Therefore when converting a measurement to the commonly used unit of dpm/100 cm^2, a multiplying area factor must be applied to the measurement. For the Ludlum instrument with a 43-1 detector of 75 cm^2 surface, multiply the value by 1.33 (i.e. 100 cm^2 divided by 75 cm^2).

The procedures are:

1. Turn the meter on and check the meter battery condition.
2. Check alpha detector mylar surface for pinholes, etc. Replace if necessary and repeat calibration.
3. As specified in Section 3.1.2.3.2, perform a function calibration check using calibrated alpha source.
4. If check is acceptable, proceed with monitoring.

5. At each designated site, monitor designated surfaces, table tops, etc., holding within ¼ inch of the surface.

6. Record data, location, cpm/cm^2 monitored on data sheet.

7. At the conclusion of the survey, transpose results to the file log, correcting to dpm/100 cm^2, using correction for detector's surface area and cpm/dpm conversion factor.

2.3.3.3 *Removable Alpha Surveys*

The Ludlum Model 2200 scaler with 43-17 detector, or a variety of other sensitive alpha detection instruments such as Model 2929 or equivalent, counts wipe samples collected during removable alpha surveys. Glass fiber filters, sized to fit the detector sample slot, are utilized as the wipe medium. A template having a 100 cm^2 surface area maybe used to standardize the surface area wiped.

The procedure is:

1. Perform function check calibration of the scaler/detector. Ensure that this measurement is within ± 10% of the value obtained from the calibration laboratory.

2. If so proceed with the survey and counting.

3. Obtain clean filters and clean envelopes for filter storage.

4. At a location to be surveyed, remove the filter from the envelope and wipe the surface covering approximately 100 cm^2. This is easily accomplished by making an "S" shaped smear for approximately 10 inches using normal swipes (approximately 2.5 cm diameter).

5. Record on envelope the date and location of the sample.

6. Upon returning to counting lab, place an unused filter in the counting unit for at least 1 minute and obtain a background count rate.

7. Repeat procedure for each used filter, extracting filter from envelope, immediately prior to counting, using tweezers and placing in the detector slot with the wiped surface facing the detector, and count for at least 1 minute.

8. Convert results from cpm/filter to dpm/filter (100 cm^2 wiped) after subtracting the blank background count.

9. Record on the alpha survey form the following information:

    A. Sample location and conditions
    B. Sample date
    C. Sampler identification
    D. Wipe count dpm/100 cm^2

10. Discard the filters and envelopes

2.3.4 Action Limits

2.3.4.1 *Respirators*

Levels greater than 100 dpm/100 cm^2 squared require re-cleaning or discarding of a respirator.

2.3.4.2 *Fixed Alpha Surveys*

Levels greater than 1,000 dpm/100 cm^2 squared require remedial action by management. ALARA criterion ensures that the RSO takes action where necessary to maintain levels as low as reasonably achievable.

2.3.4.3 2.3.4.3 *Removable Alpha Surveys*

Levels greater than 1,000 dpm/100 cm^2 squared require remedial action and decontamination. ALARA criteria ensure that the RSO takes action where necessary to maintain levels as low as reasonably achievable.

2.3.5 Records

Records of fixed and removable alpha surveys are maintained in the Radiation Safety office files. Records include:

1. Sample location/conditions
2. Sample date
3. Sampler identification
4. Fixed alpha determination – dpm/100 cm^2
5. Removable alpha determination – dpm/100 cm^2
6. Remedial action taken, where necessary

2.3.6 Quality Assurance

Calibration function checks of detector performance and visual observation of detector surfaces prior to each survey ensures counting reliability and consistency. Usage of clean containers and tweezers minimizes contamination of wipe samples. A Field log of sample I.D.'s on sample containers minimizes transposition of samples. Data review by the RSO and by the Audit Committee further assures quality maintenance.

2.4 BETA-GAMMA SURVEYS

2.4.1 Equipment

Beta/Gamma surveying instruments used for beta-gamma surveys are listed in Appendix 1 and the sources used are listed in Appendix 2.

Some instruments read directly in mrem/hour while others read in cpm (with a conversion to mrem/hour). The model 44-6 detector has a removable beta shield allowing discrimination between beta and gamma contributions. Each instrument has a manufactures user's manual which describes the function, use and capability of each instrument. These manuals must be understood before surveying proceeds. Calibration of Beta/Gamma and functional checks are performed using calibrated Cs-137 or SrY 90 sources

2.4.2 Frequency/Locations

The sites noted on Table 2.4.2-1 may be monitored on a monthly basis by of the Radiation Safety staff. During reclamation periods, only areas routinely occupied by personnel are monitored as designated by the RSO. As areas are decommission and the ability to sample those areas is removed, the RSO will document this in the files and those areas will be removed from further monitoring.

Table 2.4.2-1
Beta-gamma Survey Locations

Identification Number	Description of Possible Source of Area of Exposure	Distance from Source in cm

WM-34	Tailings Impoundment Dike 2	1
WM-35	Tailings Impoundment Dike 3	1
WM-36	Scalehouse	1
WM-37	Tailings Impoundment Dike 4	1

2.4.3 Procedures

The monitoring procedures are:

1. Check meter battery condition.

2. Check detector using a check source.

3. If the calibration function check indicates that the instrument is operating within calibration specifications, proceed with monitoring.

4. Survey each designated location on Table 2.4.2-1 and record in the field log:

   A. Site location/condition
   B. Date
   C. Instrument used
   D. Sampler's initials
   E. Meter reading (beta + gamma)
   F. Meter reading (gamma)

5. Upon returning to the office, record the mrem/hr reading into a permanent file which is maintained for beta-gamma exposure evaluation.

2.4.4 Action Levels

The ALARA concept is utilized in action levels. Responses include operative cleaning of the area or isolation of the source. The Radiation Safety Department will ensure levels ALARA.

2.4.5 Records

Records maintained in the Radiation Safety office files include:

1. Date monitored
2. Site location/condition
3. Instrument used
4. Sampler's initials
5. Beta/Gamma level, mrem/hr
6. Remedial action taken, if necessary

2.4.6 Quality Assurance

Quality of data is maintained with routine calibration and individual function checks of meter performance. Personnel utilizing equipment are trained in its usage. Records of the operational checks and calibrations are maintained in the files. The RSO routinely reviews the data and the ALARA audit committee periodically analyzes the performance of the management of the monitoring and administrative programs.

2.5 EXTERNAL GAMMA MONITORING

External gamma area monitoring is conducted at various locations around the Mill site in order to provide Radiation Safety Staff with area-specific gamma measurements. The procedures applicable to such monitoring are set out in Section 4.3 of the Mill's Environmental Protection Manual.

2.5.1 Locations and Frequency of Monitoring

External gamma measurements are taken over a quarterly interval for the twelve months of the year at all BHV locations and selected areas around the mill site (see Attachment #1 for those locations).

2.5.2 Quality Assurance

Quality assurance for external gamma measurements consists of:

2.5.2.1.1 Monitoring the container locations to ensure the TLDs have not been lost;

2.5.2.1.2 Ensuring that all containers are present when receiving or shipping to Landauer; and

2.5.2.1.3 Reviewing Landauer data for consistency and data transportation.

2.5.3 Analytical Requirements

Values reported are in millirems per week average for the monitor period (supplied by Landauer) along with a counting error term. The counting error term is calculated by:

[(sample 2 sigma) – (control mrem/week)] / (#weeks)

2.5.4 STANDARD OPERATING PROCEDURES

2.5.4.1 Equipment

External gamma is monitored at the ambient air sampling sites and other selected areas around the mill site, using the OSL badges from Landauer, Inc., or the equivalent.

2.5.4.2 Monitoring Methodology

2.5.4.2.1 The containers, each containing five TLD chips, are mounted approximately one meter above ground plane at each site with one container per site.

2.5.4.2.2 The containers loaded with TLDs are received the first of each quarter from Landauer and exchanged with those in the field.

2.5.4.2.3 A background TLD is stored in the Administration Vault as a transportation control.

2.5.4.2.4 The TLDs are returned to Landauer for processing.

2.5.4.3 Record Keeping

Data maintained in record form for external gamma is:

2.5.4.3.1 Sample period;

2.5.4.3.2 Sample location; and

External gamma levels for total radiation.

2.6 EQUIPMENT RELEASE SURVEYS

2.6.1 Policy

Materials leaving a Restricted Area going to unrestricted areas for usage must meet requirements of NRC guidance for "Decontamination of Facilities and Equipment Prior to Release for Unrestricted Use" (dated April 1993).

All material originating within the restricted area will be considered contaminated until checked by the Radiation Safety Department. All managers who desire to ship or release material from the facility will inform the RSO of their desires. The RSO has the authority to deny release of materials exceeding NRC guidance for "Decontamination of Facilities and Equipment Prior to Release for Unrestricted Use" (dated April 1993). No equipment or materials will be released without documented release by the RSO or his designee.

2.6.2 Limits

The release limits for unrestricted use of equipment and materials is contained in the NRC guidance listed above in Section 2.6.1 and are summarized as follows:

Limits for Alpha emissions for U-Nat and its daughter products are:

Average	5,000 dpm/100 cm^2
Maximum	15,000 dpm/100 cm^2
Removable	1,000 dpm/100 cm^2

Limits for Beta-gamma emissions (measured at a distance of one centimeter) for Beta/Gamma emitting radioisotopes are:

Average	0.2 mrem/hr or 5,000 dpm/100 cm^2
Maximum	1.0 mrem/hr or 15,000 dpm/100 cm^2

2.6.3 Equipment

Radiological survey instruments are listed in Appendix 1.

2.6.4 Procedures

Upon notification that materials are requested for release, the Radiation Safety Department shall inspect and survey the material. Surveys include fixed and removable alpha surveys and beta-gamma surveys. See sections 2.3 Alpha Surveys and 2.4 Beta-Gamma Surveys for a detailed breakdown on the surveying aspects and equipment used for each survey. An equipment inspection and release form, see attached, is to be prepared and signed by the RSO or his designee. Any material released from the mill will be accompanied with the appropriate release form. If contamination exceeds levels found in NRC guidance "Decontamination of Facilities and Equipment Prior to Release for Unrestricted Use", (dated April 1993), then decontamination must proceed at the direction of the RSO. If the material cannot be decontaminated, then it will not be released.

2.6.5 Records

Documented records for each released item are filed in the Radiation Safety Department files. These files shall include a completed Release Form, see attached, and a photograph of the material that is being released.

2.6.6 Quality Assurance

The RSO and the ALARA Audit Committee periodically review the policy and documented release forms to ensure policy and regulatory compliance.

2.7 Field Gamma Surveys

The field gamma surveys will be conducted in accordance with the currently approved Reclamation Plan, Section 6 of the Technical Specifications.

3.0 EQUIPMENT/CALIBRATION

All radiation detection instruments used at the Mill are sent to a qualified independent laboratory for calibration every six months. If necessary, Radiation Safety Staff can use the procedures outlined below to verify calibration.

3.1 Counters/Detectors

3.1.1 General

All radiation detectors require determination of detector optimal voltage performance or plateau operating point. The graph of voltage applied to a detector versus detector response is referred to as a plateau curve. The plateau curve typically has two rapidly sloping sections and a stable, flat region. The optimal operating point is typically located at the beginning of the flat, or flatter, section of the graph. The plateau curve is specific for a particular detector and its accompanying readout, or measuring meter, and may vary over time depending upon electronic component condition.

The equipment used to determine detector plateau curves includes:

1. Appropriate radiation sources
2. Electrostatic voltmeter
3. Radiation detecting instrument
4. Graph paper
5. Manufacturer's technical manual

The procedure is:

1. Ensure instrument batteries are fresh or fully charged, if applicable.

2. Turn the instrument on.

3. Adjust the instrument voltage control starting at voltage of 600 using electrostatic voltmeter to monitor voltage setting.

4. Expose detector to a radiation source applicable to the type of detector and in the appropriate setting.

5. Record voltage and instrument response for each adjustment of voltage applied; increments of 50 volts are adequate.

6. Repeat steps 4 and 5 until instrument response rapidly increases versus voltage level. At this point, the detector is approaching potential differentials across the electrode that may damage the detector.

7. Graph instrument response versus voltage applied.

8. Set equipment high voltage control to the optimum operating point. Record on graph voltage selected.

9. Retain graph with calibration records.

3.1.2 Function Checks

Calibration function checks are required prior to use of radiation detection instruments used at the Mill for the purpose of verifying that the instruments are operating at the same efficiency as when they were calibrated by the calibration laboratory (i.e., within +/-10%). Function checks are also used for verifying repeatability, reliability, and comparability of an instrument's measurements from one period to another. By performing function checks for extended time periods, or on a larger sample size, these goals are met.

Function checks involve two basic elements:

(1) The calibration laboratory efficiency is compared to the instrument's efficiency on the date of the function check; and
(2) The function check is verified with a check source having similar isotopic composition as the one that was used by the calibration laboratory to calibrate the instrument.

Function checks are made for all types of radiation survey instruments. The basic principle in performing a function check is measuring the radiation field using a survey instrument against a known amount of radiation from a calibrated source. These measurements are made for the specific type of radiation occurring. For example, when performing a beta/gamma survey, the instrument function check is performed using a beta/gamma check source, such as a (SrY)-90. When performing an alpha survey, use an alpha check source, such as Th-230 or Pu-239 for performing the function check.

Function checks are documented on the Calibration Check Forms (see Attachment A for copies of forms to be used) for each specific instrument. They will be maintained in the instrument's' calibration and maintenance file.

A number of radiation detection instruments are used at the Mill. An Instrument Users Manual for each instrument is maintained in the calibration files, together with calibration documentation. The Users Manuals are to be considered the primary reference for operating a particular instrument. This Standard Operating Procedure (SOP) is not intended to replace the Users Manual, but rather to supplement the Manual by providing steps to be performed for function checks. Before operating an instrument, personnel should read the Users Manual and become familiar with the instrument's operation, capabilities, and special features. Personnel will also receive on the job training on each instrument.

3.1.3 Alpha Monitors

Alpha particles travel very short distances in the air due to their high ionization ability – typically ¼ to ½ inch. Due to this limitation, alpha monitoring must be done at a distance of ¼ inch or less between the detector face and the source. Alpha monitoring, to be consistent, requires ensuring a consistent distance be utilized between the detector face and the source. Alpha detectors read out in counts per minute (cpm). A correlation relationship, known as the efficiency factor, between the meter response and the actual disintegration rate of the source is used to determine actual calibration of the meter.

Radioactivity is measured in curies (Ci), which, by definition, is 3.7×10^{10} disintegrations per second (dps), or $2.2 \text{ X } 10^{12}$ disintegrations per minute (dpm). Another measurement unit is the Becquerel, or one dps. Alpha radiation is usually monitored as dpm, per surface area measured.

Radiation survey equipment used at the Mill for alpha surveys is listed in Appendices 1 and 2.

3.1.3.1 *Calibration and Function Check Frequency*

The frequency of calibration is specified in individual instrument user manuals and manufacturer's specifications.

The following frequencies are observed for calibration and function checks of radiation detection instruments:

	Type	Calibration Frequency	Function Checks
1.	Employee scans	6 months	7 days/week
2.	Radon progeny	6 months	each use
3.	Respirator checks	6 months	each use
4.	Area fixed scans	6 months	Daily or each use
5.	Area wipe scans	6 months	Daily or each use

3.1.3.2 *Function Check Procedures – Alpha Counters and Scaler Instruments*

The following steps will be used for function checks for alpha counters and alpha scaler instruments.

1. Turn the instrument on and place a calibrated alpha check source in the detector holder on or the face of the detector.

2. Count the source for 1 minute and record this value in cpm.

3. Repeat step 2 four more times.

4. Average the five readings and divide the average in cpm by the known activity on the alpha source. This is the efficiency of the instrument and detector.

5. Compare this efficiency with the efficiency obtained from the calibration lab. If the efficiency comparison is within ±10% deviation the instrument needs is calibrated if not the instrument needs to be recalibrated.

6. If this efficiency comparison is within ±10% deviation the instrument is in calibration.

7. Proceed with monitoring activities.

3.1.3.4 *Calibration Procedures*

All radiation detection instruments used at the Mill are sent to a qualified offsite laboratory every six months for calibration. However, if additional onsite calibration is required the calibration procedures are:

1. Set the detector high voltage at the prior determined operating point using an electrostatic voltmeter.

2. For counter/scalers (radon progeny/wipes), close the detector, without source present, obtain a reading for a set time. This is a background reading.

3. Place a calibrated source for the type of radiation being measured in the source holder and obtain reading.

4. Observe the cpm for both the background and the source.

5. Subtract the cpm value of background from the cpm value of the source to obtain the net cpm.

6. Divide the net cpm value by the known dpm of the source. This is the percentage efficiency of the instrument system for this energy source.

7. By dividing 100 by this efficiency, an efficiency factor is obtained.

8. Dpm equals the cpm divided by the efficiency of the instrument detector system:

Note: *1 curie = 2.22 E + 12 dpm*
1 microcurie = 2.22 E + 6 dpm
1 picocurie = 2.22 dpm

3.1.4 Beta-gamma Monitors

Equipment utilized for beta-gamma monitoring is listed in Appendices 1 and 2.

3.1.4.1 *Function Check Procedure*

The following steps will be used for function checks on beta/gamma instruments:

1. Turn the instrument on and place the calibrated beta/gamma (SrY-90) check source on the face of the detector.

2. Let the reading stabilize to a constant value.

3. Record this value in cpm.

4. Divide this value by the known activity on the check source. This is the efficiency of the instrument and detector.

5. Compare this efficiency to the efficiency obtained from the calibration laboratory. If the efficiency comparison is within ±10% deviation the instrument needs is calibrated if not the instrument needs to be recalibrated.

6. If this efficiency comparison is within ±10% deviation the instrument is in calibration.

7. Proceed with monitoring activities.

3.1.4.2 *Calibration*

All beta-gamma survey instruments are sent out every six months for calibration. Additional calibration, if necessary, may be performed on site using techniques described in Reg. Guide 8.30, Appendix C – Beta Calibration of Survey Instruments for calibration performed by a qualified calibration laboratory using the indicated source as listed in Appendix 2.

3.1.5 Gamma Monitors

Instruments for gamma measurements are listed in Appendix 1.

3.1.5.1 *Calibration*

Independent calibration service laboratories shall perform calibrations every six months. Meters are calibrated to Cs-137 or other radioisotopes as suggested by the calibration laboratory or manufacturer. Most calibration service laboratories calibrate Beta/Gamma instruments electronically in accordance with their standard calibration procedures. However, electronic calibration basically consists of the steps described below:

1. Connect survey instrument to be calibrated to the Model 500.

2. Turn both instruments on.

3. Record high voltage reading on Model 500.

4. Set cpm and the range multiplier on the Model 500 to the desired meter deflection. The model 500 frequency controls consist of the three-digit readout, range selector, coarse tuning knob, and the fine tuning knob. The three-digit readout is in cpm times the frequency multiplier.

5. Calibrating survey instruments in cpm:

    A. Set Model 500 frequency to value that will provide a ¾ meter deflection on the survey instrument's highest count scale. Set pulse height/amplitude to twice instrument input sensitivity.

    B. Adjust the range calibration potentiometer on the survey meter to provide correct reading record.

    C. De-code Model 500 frequency to next lower value; then do the same for the survey instrument.

    D. Adjust the range calibration potentiometer for correct reading on survey instrument. Record readings.

    E. Repeat process until all ranges have been calibrated at ¾ meter deflection. Record readings.

    F. Return to highest count scale on survey meter.

    G. Set Model 500 for ¼ scale deflection readings.

    H. Survey instrument should read within ± 10% of Model 500 frequency. Record readings.

1) If readings are outside of the tolerance, re-calibrate for ¾ meter deflection.

2) Tap instrument meter lightly to check for sticky meter. Meter tolerance is ± 3% from the initial readings to the final reading.

I. Decode Model 500 to next lower scale. Check survey instruments for ¼ scale reading. Record.

6. Record input sensitivity.

A. Select the most sensitive amplitude range 0-5 mv on the Model 500.

B. Observe meter on survey instrument.

C. Increase pulse amplitude, switching to next higher range, if necessary, until the rate meter indicates a stable reading (i.e., further increase of pulse amplitude does not cause an increase in meter reading). Now, decrease pulse height until the survey instrument meter reading drops 15 ± 5%. Record this pulse height as the instrument sensitivity.

D. If your instrument has a gain or threshold control to set instrument sensitivity, set pulse height on the Model 500 to desired sensitivity level. Now adjust your instrument threshold or gain control until the rate meter reading is within 85 ± 5% of its stable reading value (see step C). Record the pulse height as instrument sensitivity.

7. Calibrating survey instrument to cps.

A. Set frequency in Model 500. Divide the Model 500 readings by 60 to convert to counts per second.

B. Repeat calibration steps as in item 5 above.

3.1.5.2 *Frequency of Calibration*

If electronic calibration is performed using the above method by the Radiation Safety Department, the Model 500 pulse generator will be sent out for calibration on an annual basis.

3.2 PERSONNEL AIR SAMPLERS

The calibration procedure for personnel air samplers involves one of three calibration procedures. Samplers will be calibrated prior to each use by one of the three methodologies: bubble tube, electronic or mass flow determinations. Air samplers may be calibrated to standard air conditions.

3.2.1 Bubble Tube Calibration Method

The Bubble Tube Calibration Method is a calibration method and does not require corrections to or from standard conditions for temperature and pressure. Personal air samplers are calibrated for the flow rate for the sampling being performed, typically 2-4 lpm.

The equipment utilized is as follows:

1. Burette – 1,000 ml capacity, 10 ml divisions
2. Support, iron, rectangular base, with rod
3. Burette clamps – 2
4. Soap solution, dish
5. Tubing, Gelman filter holder, filter media (0.8 micron glass fiber Gelman type A/E)
6. Stopwatch
7. Small screwdriver
8. Sample pump

The procedures utilized are:

1. Assemble a filter train – place a filter in an in-line filter. Attach two lengths of tubing to each connector of the in-line filter holder.

2. Make sure the Burette is clean. Clamp the 1,000 ml Burette upside down on the ring stand with the Burette clamps.

3. Attach the pump to be calibrated to one end of the filter train, connect the other end of the filter train to the small end of the 1,000 ml Burette, as per Figure 1.

4. Check all tubing connections for air tightness.

5. Pour approximately ½ inch (12 mm) of soap solution into the dish.

6. Start the pump.

7. Raise the dish up under the Burette opening, and then immediately lower the dish. This should cause a film of soap to form over the Burette opening (i.e., a bubble). Repeat this procedure until the film (bubble) will travel up the inverted Burette the length of the graduation marks on the Burette without breaking.

8. When the film (bubble) has wetted the Burette inside and will travel the entire length of the graduated area of the Burette, proceed with the actual calibration run.

9. Quickly form three bubbles and start the stopwatch when the middle bubble is at the bottom graduation line (actually the 1,000 ml mark, but for purposes here, it will be called the "zero" line).

10. Time the travel of the bubble from the zero line to the top line of the graduated distance (0 ml). Since the capacity of the Burette is 1,000 ml (1.0 liter), then the volume of air that is displaced above the bubble (i.e., needed to raise the bubble) is 1.0 liter. Stopping the stopwatch at the top mark is the time elapsed for the pump to accomplish this. The rate of rise of the bubble through the apparatus is the flow rate of air being pulled by the pump.

11. Increase or decrease the pump collection rate by adjusting the appropriate screw or knob designed for this purpose.

12. Set the pump flow collection rate to the desired valued usually between 2 and 4 liters per minute for low volume collection pumps and between 30 and 80 liters per minute for high volume collection pumps.

3.2.2 Mass Flow Method

Mass flow meters are manufactured equipment designed to measure air collection flow rates for a variety of purposes. Mass flow meters may be subject to temperature and pressure corrections of air movement depending on whether they are calibrated/manufactured for standard conditions.

Utilizing an air mass flow meter, traceable to NBS, the airflow rate of pumps can be quickly adjusted to correct standard flow rate conditions. However, the mass flow meter must be calibrated annually using a primary calibration method.

The equipment consists of the following:

1. Kurz air mass flow model 543 or equivalent
2. Suitable filter head adapter connections
3. Filter heads with filter media
4. Pump to be calibrated

Note: The meter is calibrated directly in standard air conditions – 25º C., 29.82" Hg.

The procedures utilized are:

1. Ensure pump batteries are fully charged.

2. Ensure flow meter batteries are fully charged.

3. Assemble filter train.

4. Connect (with a suitable adapter) the Kurz probe onto the filter train. Ensure an airtight seal with tape, if necessary.

5. Set the meter function switch to the highest range: 40 std liters per minute.

6. Turn the pump on.

7. Select appropriate range on the meter. (Do not allow meter needle to be forcibly pegged.)

8. Adjust the pump flow rate as necessary to desired flow rate. Allow the meter to stabilize before adjustment of the pump.

9. Meter reads directly in standard air conditions, correcting for temperature and barometric pressure.

Pump is now calibrated. Low volume pumps are set 4 lpm.

3.2.3 Electronic Calibration Method

The electronic calibration is the calibration method and does not require corrections to or from standards conditions for temperature and pressure. Personal air samplers are calibrated for the flow rate for the sampling being performed typically 2 – 4 lpm. Area Airborne high volume air samplers should be calibrated to a minimum of 40 lpm.

The equipment utilized is as follows:

1. UltraFlo Primary Gas Flow Calibrator, or equivalent
2. Soap solution
3. Tubing
4. Small screwdriver
5. Sample pump

The procedure proceeds as follows:

1. Remove the two nipples on the back of the UltraFlo Primary Gas Flow Calibrator.
2. Attach the connection tubing from the top nipple to the sample pump.
3. Turn calibrator on.
4. Turn sample pump on.

5. Press the plunger style button on top of the soap dispensing portion of the device.
6. Write down the digital reading from the calibrator device.
7. Repeat steps 5 and 6 three times.
8. Take an average of the three readings.
9. If the sample pump requires adjustment, take the screwdriver and adjust the set screw on the face of the sample pump and then repeat steps 5 through 7.
10. After the sample pump is calibrated, document the calibration on the Breathing Zone/Radon or the High Volume Calibration Sheet depending on which device is being calibrated, in the Radiation department.
11. Replace nipple caps on the back of the calibrator.

3.3 AREA AIR SAMPLERS

The calibration procedure for area air samplers involves one of the following procedures; Kurz Mass Flow, Wet Test Gas Meter, Electronic or Bubble Tube Method.

3.3.1 Kurz Mass Flow Method

Repeat procedures discussed in 3.2.2 – except – airflow rate is adjusted to 40 slpm and samplers utilized are:

1. Eberline RAS-1
2. Scientific Industries Model H25004
3. Equivalent

3.3.2 Wet Test Gas Meter Method

The wet test gas meter method utilizes a Precision Scientific wet test meter rated at one cubic foot per revolution of the main dial. This method is used to calibrate the Kurz air mass flow meter in addition to direct calibration of the area air samplers.

The procedures are:

1. Attached coupling to sampler filter assembly; secure it with tape.

2. Connect wet test meter hose to coupling.

3. Check water level of wet test meter. The needle should be on slightly above the water level.

4. Check the thermometer temperature of the wet test meter. Record this on the calibration sheet. Assume that the wet and dry bulb temperatures are the same.

5. Turn on the sampler. Check the west test meter's manometer reading. This reading is obtained by adding the left and right column values. (A typical reading might be .3). Log these values for each ball height on the "Static pressure … H_2O" column.

6. For the following sampler approximate settings, pull one cubic foot of air through the wet test meter and record the time (in seconds) for each: 20, 30, 40, and 50 lpm.

Sampler Calibration Procedures – Calculations and Equations

1. To convert the static pressure (of the manometer attached to the wet test meter) from inches of water to inches of mercury, divide the number of inches to water by 13.6. Example: 0.4/13.6-0.02941176" Hg

2. To compute the actual flow rate ("Q rate act. lpm"), first divide the number of cubic feet by the number of seconds. Example: 1 ft.^{3}/90 sec = .01111 ft.^{3}/awx. Convert the cubic feet to liters. The conversion factor is 28.317. Example: .01111 ft.^{3}/sec x 28.317 L ft.^{3} = .3146 L/sec. Multiply this by 60 to convert from seconds to minutes. Example: .3146 L/sec x 60 sec = 1888 L/m or 18.88 lpm.

3. Using the "Vapor Pressures of Water" chart, find the vapor pressure inside the wet test meter by matching the wet bulb temperature with the corresponding vapor pressure. This number is the vapor pressure at the standard wet bulb (Pvpstw).

4. Find the vapor pressure at dewpoint using this formula: Pv dewpoint = Pvpstw = 0.0003613 (td-tw) Bp (Where +d = dry bulb temp; tw = wet bulb temp; bp = barometric pressure in inches of mercury.) Assume that the dry bulb temperature and the wet bulb temperature are the same, so the difference between them will always be zero. Thus, Pv dewpoint will equal Pvpstw.

5. Determine the actual air density (D act) with this formula:

$$D\ act = \frac{1.327}{td + 459.67\ \ [(Pg-Sp) - 0.378\ (Pv\ dewpoint)]}$$

(Where td - dry bulb temp in degrees F.; Bp = barometric pressure in inches of mercury; Sp = static pressure of wet test meter in inches of mercury.)

Example:

D act = 1.327

70.5 + 459.67 [(24,8031 - 0.02941176) - 0.378 (.875)]

= 1.327

530.17 (24,773688 - 0.33075)

= (0.00250297) (24.442938)

D act = 0.06117996

Log this in "Air Density lbs/ft^3" column of log sheet.

6. Find the flow rate of the sampler at standard conditions (Q std) using this formula:

$$Q\ std = Q\ act \ \frac{D\ act}{D\ std}$$

(Where D std = .075 lbs/ft^3)

$$\text{(i.e., } Q\ std = 18.88 \ \frac{(0.06117996)}{0.075}$$

= 18.88 (0.8157328)

= 15.40

Q std = 15.40 (write this down for each position in the Q 0.075 column)

3.3.3 Bubble Tube Method

Refer to Section 3.2.1 to perform this method.

3.3.4 Electronic Calibration

Refer to Section 3.2.3 to perform this method.

4. EXPOSURE CALCULATIONS AND RECORD MAINTENANCE

4.1 PERSONNEL EXPOSURE CALCULATIONS

4.1.1 DACs for Conventional Ores

4.1.1.1 *Solubility Classes*

The solubility class, chemical form and abundance of conventional ores at the Mill, and the resulting DACs to be used are as set out in the following table:

Table 4.1.1.1-1
Solubility Class, Chemical Form and Abundance of Conventional Ores

Location	DAC	U nat	Th-230	Ra-226	Pb-210
Ore-Grind	6.00E-11	DAC is specified in 10 CFR Part 20			
Leach	2.8E-10	½ Ore, ½ Precipitation	½ Ore, ½ Precipitation	½ Ore, ½ Precipitation	½ Ore, ½ Precipitation
CCD	1.2E-11	Class D Sulfate 25%	Class W [1] Sulfate 25%	Class W [1] Sulfate 25%	Class D [1] Sulfate 25%
SX	1.2E-11	Class D Sulfate 25%	Class W [1] Sulfate 25%	Class W [1] Sulfate 25%	Class D [1] Sulfate 25%
Precipitation	5.00E-10	Class D [2] Diuranate 100%	NA	NA	NA
Yellowcake Packaging	2.20E-11	Class Y: 90 % and Class W: 10 % Oxide 100%	NA	NA	NA
Tailings	1.70E-11	Class Y Oxide 4%	Class Y [2] Oxide 32%	Class W [1] Oxide 32%	Class W [1] Oxide 32%

[1] 10 CFR Part 20, Appendix B

Ore/Grind	6.00E-11	Control Room
Yellowcake Precipitation	5.00E-10	YC Precipitation &Wet Storage
Yellowcake Packaging	2.20E-11	North YC Dryer Encl. South YC Dryer Encl. YC Pkg Enclosure YC Drying & Packaging Area Packaged YC Staging Area
Tailings	1.70E-11	Truck Shop Tailings
Yellowcake Precipitation	5.00E-10	Vanadium Circuit

4.1.2 Sampling Time

Calculate the sampling time required to detect 10% of the DAC by solving for sampling time in the following equation:

$$\frac{\text{LLD}}{(\text{Sampling Time})\ (\text{Flow Rate of Sampler})} = 0.1\ \text{DAC}$$

For example:

To detect 10% of the DAC for U-Nat, a 40 lpm air sampler would have to operate 57 minutes, assuming the sample counter has a lower level of detection of 10 dpm above background, i.e.:

$$\frac{(10\ \text{DPM})\left(\frac{\text{pCi}}{2.22\ \text{DPM}}\right)\left(\frac{\text{E-6}\ \mu\text{Ci}}{\text{pCi}}\right)}{(\text{X min.})\left(\frac{40\ \text{lit}}{\text{min.}}\right)\left(\frac{10^3\text{ml}}{\text{lit}}\right)} = \frac{2\text{E-12}\ \mu\text{Ci}}{\text{ml}}$$

X = 56.8 minutes

4.1.3 Dose Calculations (10 CFR 20.1201-20.1202)

1. Analytical results of airborne particulate samples may be obtained in several different units that need to be converted into mg soluble natural uranium to determine the weekly exposures and into uCi-hr/ml or WL-hr to determine annual exposures. The following table presents a summary of the conversions that may be necessary. The first row of the table presents the operations to be performed in the conversions. Enter the measured weight or activity, the sampler flow rate, the sampling time, and the exposure time into the first four columns. Divide the values in column 1 by the values in column 2 and column 3, and then multiply by the values in columns 4 and 5 to obtain the units in column 6, or:

$$\frac{(\text{Column 1})\ (\text{Column 4})\ (\text{Column 5})}{(\text{Column 2})\ (\text{Column 3})} = \text{Column 6}$$

UNIT CONVERSION TABLE

1	2	3	4	5	6
OPERATION	DIVIDE	DIVIDE	MULTIPLY	MULTIPLY	ANSWER
MEASURED VALUE	SAMPLER FLOW RATE	SAMPLING TIME	EXPOSURE TIME	CONSTANT	ANSWER
μg soluble U-Nat	L/min	min	hrs	1.2	mg soluble U-Nat
pCi soluble U-Nat	L/min	min	hrs	1.77	mg soluble U-Nat
pCi gross alpha	L/min	min	hrs	E-9	μCi-hrs / ML
μg U-Nat	L/min	min	hrs	6.77E-10	μCi-hrs / ML
μCi mL Radon	---	---	hrs	E7	WL-hrs

For example:

$$\frac{(10\ \mu g\ \text{Soluble U-Nat})\ (10\ \text{hrs})\ (1.2)}{(2\ \text{L/min})\ (30\ \text{min})} = 2\ \text{mg Soluble U-Nat}$$

See notes for a description of the unit conversions.

2. The table on the following page is divided into four quadrants. Different quadrants are for soluble uranium, insoluble uranium, tailings dust, and radon. Select the proper quadrant for the type of airborne particulate being sampled. Enter the area, particulate concentration, and hours of exposure in the labeled columns of the selected quadrant.

3. The protection factors are whole numbers, e.g., 10, 50, 1,000. Divide 1 by the protection factor and enter the quotient in the fourth column of each quadrant, e.g., for a protection factor of 1,000, enter 1/1,000 or 0.001 in the column. The 1/PF values are unit-less.

4. Enter the product of the airborne concentration, the hours of exposure, the time, and 1/PF in the fifth column of each quadrant. Add these values and enter the total at the bottom of the column.

5. On the dose calculations form which follows, enter the total for Soluble Uranium in the equation and calculate the corresponding mg. If a value exceeds 10 mg, an over-exposure may have occurred. If verified by a high uranium in urine results, an over-exposure has probably occurred and needs to be reported to the NRC.

6. Enter the totals for Soluble Uranium, Insoluble Uranium, Tailings Dust, and Radon in their respective equations. Perform the indicated calculations, add the fractions

together, and record as the subtotal. (Use the DAC for Th-230 or the DAC for tailings dust to determine the contribution of tailings dust to the subtotal.) If a subtotal exceeds 1, an over-exposure may have occurred. If verified by a high uranium in urine result, an over-exposure has probably occurred and needs to be reported to the NRC.

7. Enter the TLD determinations of whole body dose as the Deep Dose Equivalent on the form. If the Deep Dose Equivalent exceeds 5 rems, an over-exposure may have occurred and needs to be reported to the NRC.

8. If the Deep Dose Equivalent exceeds 0.5 rem and the subtotal exceeds 0.1, calculate the Total Effective Dose Equivalent by adding the Deep Dose Equivalent to the product of 5 rems times the subtotal and enter on the form. If the total effective dose equivalent exceeds 5 rems, an over-exposure may have occurred and may have to be reported to the NRC.

DOSE CALCULATIONS (10 CFR 20.1201 + 20.1202)

DOSE CALCULATIONS (10 CFR 20.1201 + 20.1202)

________	________	________	________	________
Name	Soc. Sec. No.	Co. I.D. No.	Week	Year

Weekly Soluble Uranium   (µCi-hr) (1.77E9) / (mL)   = ____________ mg

Limit   10 mg

Annual Soluble Uranium   (µCi-hr / mL) / (2000 hr) (5E-10)   = ____________

Annual Insoluble Uranium   (µCi-hr / mL) / (2000 hr) (2E-11)   = ____________

Annual Tailings Dust   (µCi-hr / mL) / (2000 hr) (*)   = ____________

* = DAC for Th-230 = 6E-12;
or = DAC for tailings dust.

Annual Radon with Daughters Present   (WL-hr) / (2000 hr) (0.33 WL)   = ____________

Subtotal   ____________

Limit   1

Deep Dose Equivalent = TLD Whole Body Dose in rem =   ____________ rem

Limit   5 rem

If the Deep Dose Equivalent is > 0.5 rem
and
the Subtotal is > 0.1, then

Total Effective Dose Equivalent = Deep Dose Equivalent + Committed Effective Dose Equivalent

= (rem) + (5 rem) (Subtotal) = ____________ rem

Limit   5 rem

DOSE CALCULATIONS (10 CFR 20.1201 + 20.1202)

Notes:µ

1. PF = Respiratory Protection Factor.

2. The 10 mg soluble uranium per week limit in 10 CFR Part 20.1201 is more restrictive than the (40 hour) (DAC) limit for natural uranium, thus compliance is based on 10 mg per week.

3. The conversion of uCi-hr/mL to mg natural uranium is the product of:

   (air concentration) (hours of exposure) (breathing rate for light work) (conversion of minutes to hours) (specific activity of natural uranium) (conversion of ug to mg) which is:

$$\left(\frac{\mu Ci\text{-}hr}{mL}\right)\left(\frac{2E4\ mL}{min}\right)\left(\frac{60\ min}{hr}\right)\left(\frac{\mu g}{6.77E\text{-}7\ \mu Ci}\right)\left(\frac{E\text{-}3\ mg}{\mu g}\right) =$$

$$\left(\frac{\mu Ci\text{-}hr}{mL}\right)(1.77E9) = mg\ U\text{-}Nat$$

   Thus to obtain mg natural uranium, multiply the µCi-hr/mL by 1.77E9.

4. Soluble Uranium DAC (Class D) = 5E-10 µCi/mL
   Insoluble Uranium DAC (Class Y) = 2E-11 µCi/mL
   Thorium-230 DAC (Class Y) = 6E-12 µCi/mL
   Radon with Daughters DAC = 3E-8 µCi/mL = 0.33 WL
   Tailings Dust DAC is a Site Specific Value = µ5. Description of unit conversions:

   a. ug soluble U-Nat → mg soluble U-Nat

$$\left(\frac{\mu g}{(L/min)\ (min\ sampler)\ (E3\ mL/L)}\right)\left(\frac{E\text{-}3\ mg}{\mu g}\right)\left(\frac{60\ min}{hr}\right)(hr\ exposure) =$$

$$\left(\frac{\mu g}{(L/min)\ (min\ sampler)}\right)(hr\ exposure)\ (1.2) = mg\ soluble\ U\text{-}Nat$$

   b. pCi soluble U-Nat → mg soluble U-Nat

$$\left(\frac{\text{pCi}}{(\text{L/min})\ (\text{min sampler})\ \left(\frac{\text{E3 mL}}{\text{L}}\right)}\right)\left(\frac{\text{E-9 mCi}}{\text{pCi}}\right)\left(\frac{\text{mg}}{\text{6.77E-7 mCi}}\right)\left(\frac{\text{2E4 mL}}{\text{min}}\right)\rightarrow$$

$$\left(\frac{\text{60 min}}{\text{hr}}\right)(\text{hr exposure}) =$$

$$\left(\frac{\text{pCi}}{(\text{L/min})\ (\text{min sampler})}\right)(\text{hr exposure})\ (1.77) = \text{mg soluble U-Nat}$$

c. pCi gross alpha $\rightarrow$ µCi-hr

$$\left(\frac{\text{pCi}}{\left(\frac{\text{L}}{\text{min}}\right)(\text{min sampler})\left(\frac{\text{E-3 mL}}{\text{L}}\right)}\right)\left(\frac{\text{E-6 }\mu\text{Ci}}{\text{pCi}}\right)(\text{hr exposure}) =$$

$$\left(\frac{\text{pCi}}{\left(\frac{\text{L}}{\text{min}}\right)(\text{min sampler})}\right)(\text{hr exposure})\ (\text{E-9}) = \frac{\mu\text{Ci-hr}}{\text{mL}}$$

d. µg U-Nat $\rightarrow \frac{\mu\text{Ci- hr}}{\text{mL}}$

$$\left(\frac{\mu\text{g}}{\left(\frac{\text{L}}{\text{min}}\right)(\text{min sampler})\left(\frac{\text{E3 mL}}{\text{L}}\right)}\right)\left(\frac{\text{6.77E-7 }\mu\text{Ci}}{\mu\text{g}}\right)(\text{hr exposure}) =$$

$$\left(\frac{\mu\text{Ci}}{\left(\frac{\text{L}}{\text{min}}\right)(\text{min sampler})}\right)(\text{hr exposure})\ (\text{6.77E-10}) = \frac{\mu\text{Ci-hr}}{\text{mL}}$$

e. $\frac{\mu\text{Ci}}{\text{mL}}$ of Radon-222 $\rightarrow$ WL

$$\left(\frac{\mu\text{Ci}}{\text{mL}}\right)\left(\frac{\text{E6 pCi}}{\mu\text{Ci}}\right)\left(\frac{\text{E3 mL}}{\text{L}}\right)\left(\frac{\text{L-WL}}{\text{E2 pCi}}\right) =$$

$$\left(\frac{\mu\text{Ci}}{\text{mL}}\right)(\text{E7}) = \text{WL}$$

4.2 Personnel Exposure Files

The Company will generate and maintain individual exposure records for each employee that works at the White Mesa Mill. The record system will be designed to meet the specifications of the Federal Code of Regulations 10 CFR Part 20.

When an employee is hired, a file will be generated specifically for that individual. All records that are to be in the radiation exposure file will be maintained during the term of employment. When the employee terminates, all records will be preserved until the NRC authorizes their disposition.

Personnel exposure records will be maintained at the mill site and will be accessible only to the employee and the Radiation Safety staff. No copy of the exposure history will be furnished to anyone outside of the Radiation Safety Department without a signed consent form from the employee.

Contents of the exposure file:

Each personnel exposure file will contain the following records:

1. Information Sheet – Each information sheet will include the following information:

    A. Employee's full name
    B. Birth date
    C. Social Security number
    D. Date of hire
    E. Date of termination

2. Record of Urinalyses – A multiple entry log of all urinalyses conducted at this work site will include the following information:

    A. Employee's full name
    B. Sample dates
    C. Sample identification number
    D. Concentration of uranium in μg/l
    E. An entry for any quality assurance "spikes" entered in μg/l

3. Internal personnel Exposure Records – These will be calculated and prepared using the forms above or by the computer and the printout will be used as the permanent record in the exposure file. The internal exposure records will contain the following information:

    A. Employee's full name
    B. Social Security number

C. Birth date
D. Exposure to airborne uranium expressed in both µCi and percent MPC
E. Any breathing zone samples collected for airborne uranium to be expressed in µCi
F. Radon daughters expressed in working levels (WL) and period of exposure (date)

4. External Exposure Record (OSL, Dosimeter) – The date received from the Dosimeter contractor will be posted to the Dosimeter record in the exposure file. The following information will be included on the Dosimeter record:

   A. Employee's full name
   B. Birth date
   C. Social Security number
   D. Period of exposure (dates)
   E. Exposure in millirems (mrem) for a given period
   F. Total accumulated exposure while at the White Mesa Mill
   G. Identification number of the Dosimeter badge

5. Record of Exposure from Previous Employment (NRC form 4 or similar) – A record of occupational exposures that occurred prior to employment at the mill must be obtained for each employee. If no such exposure record is available, the employee must sign a statement to that affect. If previous exposure records were kept, a copy must be secured and placed in the individual's file.

6. Reports of Over-exposure – If an individual has been found to be over-exposed, the RSO will draft a letter of explanation. The report will explain the circumstances and/or reasons for the over-exposure. It will also state any actions taken to correct the problem or to prevent future over-exposures. The report must be placed in the individual's exposure file.

5. RADIATION WORK PERMITS

5.1 General

A Radiation Work Permit ("RWP") system has been established for non-routine activities where there is a potential for a significant radiation exposure, or for certain routine activities where there is a potential to spread radioactive materials.

Specifically, an RWP is required for:

a) All non-routine maintenance work, or work for which there is no effective procedure, which may, by the determination of the RSO, exceed 25% of the R313-15 limits;

b) All routine work, not covered by an procedure, that could involve the spread of radioactive materials; and

c) The receipt, handling or processing of any alternate feed material or other radioactive material, which has been determined by the RSO, not to fall within an existing operating procedure.

An RWP may also be used on a temporary basis for routine activities in lieu of an procedure, while a procedure is being developed for the activity.

5.2 All Non-Routine Activities Require RSO Review

All non-routine activities require review by the RSO. The RSO will advise the Mill Manager on a regular basis of any activities that require an RWP.

5.3 Radiation Work Permit

The RWP is a form that describes the work to be performed, the location, duration and personnel involved, and the radiological controls needed, such as respirator, urine samples, breathing zone monitoring, time limitations for the activity, etc. The form must also have an area for the RSO, or his designee's, signature. A copy of a form of RWP is attached.

5.4 Procedure for Obtaining a Radiation Work Permit

The procedure for obtaining an RWP is:

a) When RWP-type work is to be performed, the Shift Foreman, Maintenance Superintendent or other supervisory personnel shall complete the top portion of the RWP, which will provide information on the specific work locations, estimated work duration, type of work to be performed, and personnel utilized, and present it to the RSO;

b) The RSO will indicate the radiological controls needed based on the information given and the safety of personnel. The RSO or his designee will provide the necessary surveillance and respiratory protection equipment;

c) No work can be performed until the RSO or his designee has approved the RWP;

d) Any maintenance or RWP jobs done in the yellowcake dryer or packaging enclosures will require a member of the Radiation Staff to be present for the duration of the job;

e) All supervisors will be given training in and copies of the requirements for using RWPs, with the permits remaining on file for five years; and

f) Any supervisor found to be knowingly and willfully violating these procedures will be issued a written warning, and the situation will be reviewed by appropriate management for remedial action.

White Mesa Mill
Radiation Survey of Equipment Released for Unrestricted Use

All equipment or material released from the White Mesa Mill to an unrestricted area must be surveyed for release in accordance with the following procedure.

1. Monitor for Gross alpha contamination with the appropriate survey meter.
2. If calculated assay exceeds 1,000 dpm/100cm^2, then perform swipe analysis at applicable points.
3. Decontaminate if a removable alpha exceeds 1,000 dpm/100cm^2 or fixed alpha exceeds 5,000 dpm/100cm^2.
4. Release equipment or material if alpha contamination and Beta-Gamma levels are below the following limit:

Removable alpha – 1,000 dpm/100cm^2
Fixed alpha- 5,000 dpm/100cm^2 average
15,000 dpm/100cm^2 maximum

Beta-Gamma- 0.2 mr/hr @1cm average
1.0 mr/hr @ 1cm maximum

TAILINGS COVER DESIGN

1.0 SOIL COVER DESIGN

A six-foot thick soil cover for the uranium tailings Cells 2, 3 and 4A was designed using on-site materials that will contain tailings and radon emissions in compliance with regulations by the United States Nuclear Regulatory Commission (NRC) and by reference, the Environmental Protection Agency (EPA). The cover consists of a one-foot thick layer of clay, available from within the site boundaries (Section 16), below two-feet of random fill, available from stockpiles on-site. The clay is underlain with three feet (minimum) random fill soil, also available on site. The cover layers will be compacted to 95 percent maximum dry density using standard construction techniques. In addition to the soil cover, a minimum 3 inch (on the cover top) to 12-inch (on the cover slopes) layer of riprap material will be placed over the compacted random fill to stabilize slopes and provide long-term erosion resistance.

Uranium tailings soil cover design requirements for agency compliance include:

- Attenuate radon flux to an acceptable level (20 picoCuries-per meter squared-per second [pCi/m^2/sec]) (NRC, 1989);
- Minimize infiltration into the reclaimed tailings cells;
- Maintain a design life of up to 1,000 years and at least 200 years; and
- Provide long-term slope stability and geomorphic durability to withstand erosional forces of wind, the probable maximum flood event, and a horizontal ground acceleration of 0.1g due to seismic events.

Several models/analyses were utilized in simulating the soil cover effectiveness: radon flux attenuation, hydrologic evaluation of infiltration, freeze/thaw effects, soil cover erosion protection, and static and pseudostatic slope stability analyses. These analyses and results are discussed in detail in Sections 1.1 through 1.5. The soil cover configuration presented above consisting of (from top to bottom); a minimum three inches of riprap material on the top cover, two feet compacted random fill, one foot compacted clay, and a minimum of three feet random fill beneath the clay meets NRC and EPA requirements.

The soil cover design for the uranium tailings Cells 2, 3, and 4A was developed based on two construction options:

- An integrated soil cover over Disposal Cells 2, 3, and 4A; and
- A cover over Cells 2 and 3, where Cell 4A tailings are excavated and placed into Cell 3.

For modeling/analysis purposes it was assumed that the physical and radiological parameters of the tailings in Cells 2, 3, and 4A are not dependent on the tailing volume in each individual cell. Therefore, each of the two construction options above resulted in the same soil cover configuration. The only variation between the options is in the required volumes of cover materials, which is dependent only on the surface area to be covered (see Section 1.7).

The final grading plans for the two options are presented on Figures 1 and 2, respectively. As indicated on the figures, the top slope of the soil cover will be constructed at 0.2 percent and the side slopes, as well as transitional areas between cells, will be graded to five horizontal to one vertical (5H:1V).

A minimum of three feet random fill is located beneath the compacted fill and clay layers (see cross-sections on Figures 3 and 4. The purpose of the fill is to raise the base of the cover to the desired subgrade elevation. In many areas, the required fill thickness will be much greater. However, the models and analyses were performed conservatively assuming only a three-foot layer. For modeling purposes, this lower, random fill layer was considered as part of the soil cover for performing the radon flux attenuation calculation, as it effectively contributes to the reduction of radon emissions (see Section 1.1). The fill was also evaluated in the slope stability analysis (see Section 1.5). However, it is not defined as part of the soil cover for other design calculations (infiltration, freeze/thaw, and cover erosion).

The following sections describe design considerations, complete with calculations performed and parameters utilized, in developing the tailings impoundment soil cover to meet regulatory requirements.

1.1 Radon Flux Attenuation

The Environmental Protection Agency (EPA) rules in 40 Code of Federal Regulation (CFR) Part 192 require that a "uranium tailings cover be designed to produce reasonable assurance that the radon-222 release rate would not exceed 20 pCi/m^2/sec for a period of 1,000 years to the extent reasonably achievable and in any case for at least 200 years when averaged over the disposal area over at least a one year period" (NRC, 1989). NRC regulations presented in 10 CFR Part 40 also restrict radon flux to less than 20 pCi/m^2/sec. The following sections present the analyses and design for a soil cover which meets this requirement.

1.1.1 Predictive Analysis

The soil cover for the tailings cells at White Mesa Mill was evaluated for attenuation of radon gas using the digital computer program, RADON, presented in the NRC's Regulatory Guide 3.64 (Task WM 503-4) entitled "Calculation of Radon Flux Attenuation by Earthen Uranium Mill Tailings Covers". The RADON model calculates radon-222 flux attenuation by multi-layered earthen uranium mill tailings covers, and determines the minimum cover thickness required to meet NRC and EPA standards. The RADON model uses the following soil properties in the calculation process:

- Soil layer thickness [centimeters (cm)];
- Soil porosity (percent);
- Density [grams-per-cubic centimeter (gm/cm^3)];
- Weight percent moisture (percent);
- Radium activity (piC/g);
- Radon emanation coefficient (unitless); and

- Diffusion coefficient [square centimeters-per-second (cm^2/sec)].

Physical and radiological properties for tailings and random fill were analyzed by Chen and Associates (1987) and Rogers and Associates (1988). Clay physical data from Section 16 was analyzed by Advanced Terra Testing (1996) and Rogers and Associates (1996). See Appendix A for laboratory test data results.

The Radon model was performed for the following cover section (from top to bottom):

- two feet compacted random fill;
- one foot compacted clay; and
- a minimum of three feet random fill occupying the freeboard space between the tailings and clay layer.

The three layers are compacted to 95 percent maximum dry density. The top riprap layer was not included as part of the soil cover for the radon attenuation calculation.

The results of the RADON modeling exercise show that the uranium tailings cover configuration will attenuate radon flux emanating from the tailings to a level of 17.6 $pCi/m^2/sec$. This number was conservatively calculated as it takes into account the freeze/thaw effect on the uppermost part (6.8 inches) of the cover (Section 1.3). The soil cover and tailing parameters used to run the RADON model, in addition to the RADON input and output data files, are presented in Appendix B as part of the Radon Calculation brief. Based on the model results, the soil cover design of six-foot thickness will meet the requirements of 40 CFR Part 192 and 10 CFR Part 40.

1.1.2 Empirical Data

Radon gas flux measurements have been made at the White Mesa Mill tailings piles over Cells 2 and 3 (see Appendix C). These cells are currently covered with three to four feet of random fill. Radon flux measurements, averaged over the covered areas, were as follows (EFN, 1996):

	1994	1995
Cell 2	7.7 pCi/m^2 sec	6.1 pCi/m^2 sec
Cell 3	7.5 pCi/m^2 sec	11.1 pCi/m^2 sec.

Empirical data suggest that the random fill cover, alone, is currently providing an effective barrier to radon flux. Thus, the proposed tailings cover configuration, which is thicker, moisture adjusted, contains a clay layer and is compacted, is expected to attenuate the radon flux to a level below that predicted by the Radon model. The field radon flux measurements confirm the conservatism of the cover design. This conservatism is necessary, however, to guarantee compliance with NRC regulations under long term climatic conditions over the required design life of 200 to 1,000 years.

1.2 Infiltration Analysis

The tailings ponds at White Mesa Mill are lined with synthetic geomembrane liners which could lead to the long-term accumulation of water from infiltration of precipitation. Therefore, the soil cover was evaluated to estimate the potential magnitude of infiltration into the capped tailings ponds. The Hydrologic Evaluation of Landfill Performance (HELP) model, Version 3.0 (EPA, 1994) was used for the analysis. HELP is a quasi two-dimensional hydrologic model of water movement across, into, through, and out of capped and lined impoundments. The model utilizes weather, soil, and engineering design data as input to the model, to account for the effects of surface storage, snowmelt, run-off, infiltration, evapotranspiration, vegetative growth, soil moisture storage, lateral subsurface drainage, and unsaturated vertical drainage on the specific design, at the specified location.

The soil cover was evaluated based on a two-foot compacted random fill layer over a one-foot thick, compacted clay layer. The soil cover layers were modeled based on material placement at a minimum of 95 percent of the maximum dry density, and within two percent of the optimum moisture content per American society for Testing and Materials (ASTM) requirements. The top riprap layer and the bottom random fill layer were not included as part of the soil cover for infiltration calculations.

The random fill will consist of clayey sands and silts with random amounts of gravel and rock-size materials. The average hydraulic conductivity of several samples of random fill was calculated, based on laboratory tests, to be 8.87×10^{-7} cm/sec. The hydraulic conductivity of the clay source from Section 16 was measured in the laboratory to be 3.7×10^{-8} cm/sec. Geotechnical soil properties and laboratory data are presented in Appendix A.

Key HELP model input parameters include:

- Blanding, Utah, monthly temperature and precipitation data, and HELP model default solar radiation, and evapotranspiration data from Grand Junction, Colorado. Grand Junction is located north east of Blanding in similar climate and elevation;
- Soil cover configuration identifying the number of layers, layer types, layer thickness', and the total covered surface area;
- Individual layer material characteristics identifying saturated hydraulic conductivity, porosity, wilting point, field capacity, and percent moisture; and
- Soil Conservation Service runoff curve numbers, evaporative zone depth, maximum leaf area index, and anticipated vegetation quality.

Water balance results, as calculated by the HELP model, indicate that precipitation would either run-off the soil cover or be evaporated. Thus, model simulations predict zero infiltration of surface water through the soil cover, as designed. These model results are conservative and take into account the freeze/thaw effects on the uppermost part (6.8 inches) of the cover (Section 1.3). The HELP model input and output for the tailings soil cover are presented in the HELP Model calculation brief included as Appendix D.

1.3 Freeze/Thaw Evaluation

The tailings soil cover of one foot of compacted clay covered by two feet of random fill was evaluated for freeze/thaw impacts. Repeated freeze/thaw cycles have been shown to increase the bulk soil permeability by breaking down the compacted soil structure.

The soil cover was evaluated for freeze/thaw effects using the modified Berggren equation as presented in Aitken and Berg (1968) and recommended by the NRC (U.S. Department of Energy, 1988). This evaluation was based on the properties of the random fill and clay soil, and meteorological data from both Blanding, Utah and Grand Junction, Colorado.

The results of the freeze/thaw evaluation indicate that the anticipated maximum depth of frost penetration on the soil cover would be less than 6.8 inches. Since the random fill layer is two feet thick, the frost depth would be confined to this layer and would not penetrate into the underlying clay layer. The performance of the soil cover to attenuate radon gas flux below the prescribed standards, and prevent surface water infiltration, would not be compromised. The input data and results of the freeze/thaw evaluation are presented in the Effects of Freezing on Tailings Covers Calculation brief included as Appendix E.

1.4 Soil Cover Erosion Protection

A riprap layer was designed for erosion protection of the tailings soil cover. According to NRC guidance, the design must be adequate to protect the soil/tailings against exposure and erosion for 200 to 1,000 years (NRC, 1990). Currently, there is no standard industry practice for stabilizing tailings for 1,000 years. However, by treating the embankment slopes as wide channels, the hydraulic design principles and practices associated with channel design were used to design stable slopes that will not erode. Thus, a conservative design based on NRC guidelines was developed. Engineering details and calculations are summarized in the Erosion Protection Calculation brief provided in Appendix F.

Riprap cover specifications for the top and side slopes were determined separately as the side slopes are much steeper than the slope of the top of the cover. The size and thickness of the riprap on the top of the cover was calculated using the Safety Factor Method (NUREG/CR-4651, 1987), while the Stephenson Method (NUREG/CR-4651, 1987) was used for the side slopes. These methodologies were chosen based on NRC recommendations (1990).

By the Safety Factor Method, riprap dimensions for the top slope were calculated in order to achieve a slope "safety factor" of 1.1. For the top of the soil cover, with a slope of 0.2 percent, the Safety Factor Method indicated a median diameter (D_{50}) riprap of 0.28 inches is required to stabilize the top slope. However, this dimension must be modified based on the long-term durability of the specific rock type to be used in construction. The suitability of rock to be used as a protective cover must be assessed by laboratory tests to determine the physical characteristics of the rocks. The sandstones from the confluence of Westwater and Cottonwood Canyons require an oversizing factor of 25 percent. Therefore, riprap created from this sandstone source should have a D_{50} size of at least 0.34 inches and should have an overall layer thickness of at least three inches on the top of the cover.

Riprap dimensions for the side slopes were calculated using Stephenson Method equations. The side slopes of the cover are designed at 5H:1V. At this slope, Stephenson's Method indicated the unmodified riprap D_{50} of 3.24 inches is required. Again assuming that the on-site sandstone will be used, the modified D_{50} size of the riprap should be at least 4.05 inches with an overall layer thickness of at least 12 inches.

The potential of erosion damage due to overland flow, sheetflow, and channel scouring on the top and side slopes of the cover, including the riprap layer, has been evaluated. Overland flow calculations were performed using site meteorological data, cap design specifications, and guidelines set by the NRC (NUREG/CR-4620, 1986). These calculations are included in Appendix F. According to the guidelines, overland flow velocity estimates are to be compared to "permissible velocities", which have been suggested by the NRC, to determine the potential for erosion damage. When calculated, overland flow velocity estimates exceed permissible velocities, additional cover protection should be considered. The permissible velocity for the tailings cover (including the riprap layer) is 5.0 to 6.0 feet-per-second (ft./sec.) (NUREG/CR 4620). The overland flow velocity calculated for the top of the cover is less than 2.0 ft/sec., and the calculated velocity on the side slopes is 4.9 ft/sec. Therefore, the erosion potential of the slopes, due to overland flow/channel scouring, is within acceptable limits and no additional erosion protection is required.

1.5 Slope Stability Analysis

Static and pseudostatic analyses were performed to establish the stability of the side slopes of the tailings soil cover. The side slopes are designed at an angle of 5H:1V. Because the side slope along the southern section of Cell 4A is the longest and the ground elevation drops rapidly at its base, this slope was determined to be critical and is thus the focus of the stability analyses.

The computer software package GSLOPE, developed by MITRE Software Corporation, has been used for these analyses to determine the potential for slope failure. GSLOPE applies Bishop's Method of slices to identify the critical failure surface and calculate a factor of safety (FOS). The slope geometry and properties of the construction materials and bedrock are input into the model. These data and drawings are included in the Stability Analysis of Side Slopes Calculation brief included as Appendix G. For this analysis, competent bedrock is designated at 10 feet below the lowest point of the foundation [i.e., at a 5,540-foot elevation above mean sea level (msl)]. This is a conservative estimate, based on the borehole logs supplied by Chen and Associates (1979), which indicate bedrock near the surface.

1.5.1 Static Analysis

For the static analysis, a FOS of 1.5 or more was used to indicate an acceptable level of stability. The calculated FOS is 2.91, which indicates that the slope should be stable under static conditions. Results of the computer model simulations are included in Appendix G.

1.5.2 Pseudostatic Analysis (Seismicity)

The slope stability analysis described above was repeated under pseudostatic conditions in order to estimate a FOS for the slope when a horizontal ground acceleration of 0.10g is applied. The slope geometry and material properties used in this analysis are identical to those used in the stability analysis. A FOS of 1.0 or more was used to indicate an acceptable level of stability under pseudostatic conditions. The calculated FOS is 1.903, which indicates that the slope should be stable under dynamic conditions. Details of the analysis and the simulation results are included in Appendix G.

Recently, Lawrence Livermore National Laboratory (LLNL) published a report on seismic activity in southern Utah, in which a horizontal ground acceleration of 0.12g was proposed for the White Mesa site. The evaluations made by LLNL were conservative to account for tectonically active regions that exist, for example, near Moab, Utah. Although, the LLNL report states that "...[Blanding] is located in a region known for its scarcity of recorded seismic events," the stability of the cap design slopes using the LLNL factor was evaluated. The results of a sensitivity analysis reveal that when considering a horizontal ground acceleration of 0.12g, the calculated FOS is 1.778 which is still above the required value of 1.0, indicating adequate safety under pseudostatic conditions. This analysis is also included in Appendix G.

1.6 Cover Material/Cover Material Volumes

Construction materials for reclamation will be obtained from on-site locations. Fill material will be available from the stockpiles that were generated from excavation of the cells for the tailings facility. If required, additional materials are available locally to the west of the site. A clay material source, identified in Section 16 at the southern end of the White Mesa Mill site, will be used to construct the one-foot compacted clay layer. Riprap material will be taken from on-site sandstone, located at the confluence of Westwater and Cottonwood Canyons.

Material quantities have been calculated for each of the components of the reclamation cover. Volume estimates were made for the two soil cover design options, as follows:

- Option 1: an integrated soil cover which incorporates Disposal Cells 2, 3, and 4A, and
- Option 2: a cover which includes Cells 2 and 3, where Cell 4A tailings have been excavated and placed in Cell 3.

The quantity of random fill required to bring the pond elevation up to the soil cover subgrade and construct the final slope was not calculated. This layer will be a minimum of three feet in depth and is dependent on the final tailings grade, which is not known.

For Design Option 1, construction will require the following approximate quantities of materials:

Material	**Volume (cubic yards)**
Clay	365,082
Random Fill	737,717
Riprap (top of cover)	82,762
Riprap (side slopes)	41,588

For Design Option 2, construction will require the following approximate quantities of materials:

Material	**Volume (cubic yards)**
Clay	289,514
Random Fill	585,334
Riprap (top of cover)	64,984
Riprap (side slopes)	35,885

Material quantities calculations are provided in Appendix H as part of the Tailings Cover Material Volume Calculation brief.

Dear Mr. Sealy:

We have completed the tests ordered on the four samples shipped to us. The results are as follows:

Sample	Radium pCi/gm	Emanation Fraction	Diffusion Coeffic.	(g/cm^3) Density	Moisture	Saturation
Tailings	981±4	0.19±0.01	2.0E-02	1.45	13.2	0.39
			8.4E-03	1.44	19.1	0.56
Composite (2,3,&5)			1.6E-02	1.85	6.5	0.40
			4.5E-04	1.84	12.5	0.75
Site #1			1.6E-02	1.85	8.1	0.48
			1.4E-03	1.84	12.6	0.76
Site #4			1.1E-02	1.65	15.4	0.63
			4.2E-04	1.65	19.3	0.80

The samples will be shipped back to you in the next few weeks. If you have any questions regarding the results on the samples please feel free to call.

Sincerely,

Renee Y. Bowser
Lab Supervisor

Dear Mr. Sealy:

The tests for radium content and radon emanation coefficient in the following samples have been completed and the results are as follows:

Sample	Radium (pCi/g)	Radon Emanation Coefficient
Random (2,3 & 5)	1.9 ± 0.1	0.19 ± 0.04
Site 1	2.2 ± 0.1	0.20 ± 0.03
Site 4	2.0 ± 0.1	0.11 ± 0.04

If you have any questions regarding these results please feel free to call Dr. Kirk Nielson or me.

Sincerely,

Renee Y. Bowser
Lab Supervisor

Dear Ms. Anderson:

Enclosed are the results from the radium content, specific gravity, and radon emanation and diffusion coefficient measurements that were performed on the sample sent to our laboratory. We will be returning the sample within the month.

If you have any questions or if we can be of further assistance, please call.

Sincerely,

Bret Rogers

SUMMARY OF LABORATORY TEST RESULTS

HOLE	DEPTH (FEET)	NATURAL MOISTURE (%)	NATURAL DRY DENSITY (PCF)	ATTERBERG LIMITS		UNCONFINED COMPRESSIVE STRENGTH (PSF)	TRIAXIAL SHEAR TESTS		PERCENT PASSING NO. 200 SIEVE	SOIL TYPE
				LIQUID LIMIT (%)	PLASTICITY INDEX (%)		DEVIATOR STRESS (PSF)	CONFINING PRESSURE (PSF)		
76	0 - 1	4.5		21	5				78	Sandy silt
	9.5 - 10	4.4			NP				26	Silty, gravelly sand
77	7.5 - 8	8.6		30	15				71	Sandy clay
79	0 - 1	4.1		20	5				83	Sandy silt
	5 - 5.5	5.5			NP				41	Calcareous sandy clay
80	4.5 - 7			39	20				78	Calcareous sandy clay
	8 - 8.5	10.1		40	20				86	Weathered claystone
81	3 - 4	6.3		26	8				64	Silty, sandy clay
83	4 - 6			24	7				64	Sandy, clayey silt
84	0 - 2			18	2				65	Sandy silt
	9 - 9.5	2.7			NP				27	Silty sand
86	8 - 8.5	2.6			NP				12	Sandstone
87	0 - 1	3.1		16	1				61	Sandy silt
89	0 - 3			21	5				66	Sandy silt
90	8 - 8.5	12.9		35	15				61	Weathered claystone
92	0 - 1	5.9		21	5				80	Sandy silt
94	5 - 5.5	13.7		27	10				68	Sandy clay
95	6 - 7			23	5				62	Sandy silt
96	0 - 2	5.2		21	4				79	Sandy silt
	8.5 - 9.5			32	6				66	Calcareous sandy clay
98	0 - 1	3.8		20	5				74	Sandy silt
	4 - 4.5	17.8		49	25				76	Weathered claystone
99	8 - 9.5			40	20				89	Weathered claystone

KEY:

USCS	United Soil Classification System group symbol, ASTM D 2487 or D2488 (For rocks, symbol indicates geologic unit)
ASTM	Test designations of the American Society for Testing and Materials
BENDIX	"Data Collection for Engineering for the Uranium Mill Tailings Site and Adjacent Peripheral Properties, Monticello, Utah," Bendix Field Engineering Corporation, September 1988
D&M	"Final Report, Monticello Remedial Action Project, 1991 Millsite Characterization Study," Dames & Moore, September 17, 1991
*	Sample taken from a test pit excavated next to the designated borehole.
[?]	Questionable value or identification

MATERIAL TYPE:

Tails-snd	Tailings sands
Tails-slm	Tailings slimes
Tails-snd/slm	Tailings sands and slimes, interbedded
Tails-snd&slm	Tailings sands and slimes, mixed
Cover	Cover material in place on tailings piles
MVP spoils	Material removed from Monticello Vicinity Properties
Alluvium	Miscellaneous surficial deposits, mostly stream-laid
Loess	Windblown fine-grained deposits
Shale	Mancos Shale, usually weathered
Sandstone	Dakota Sandstone
Fill	Miscellaneous man-made fill

OTHER TESTS:

Mod Proct	Modified Proctor compaction
Unconf Comp	Unconfined compressive strength
Dir Shear	Direct shear, consolidated-drained
Triax-CUPP	Triaxial shear, consolidated-undrained with pore pressure measurements
Consol	One-dimensional consolidation
Perm	Permeability, falling-head or flexible-membrane
CMR	Capillary moisture rise

SAMPLE TYPES:

BULK	Disturbed bag sample of loose cuttings or material from test pit.
SS	Disturbed sample from 2.0" O.D. standard split-spoon drive sampler
ST	Relatively undisturbed sample from 3.0" O.D. thin-walled (Shelby) tube sampler
U	Relatively undisturbed sample from Dames & Moore Type "U" ring-lined drive sampler

All data in this table compiled or interpreted from consultant's reports by R.N. Morris, Chem-Nuclear Geotech, Inc., October 1991. Checked by L.H. Golden & corrected by R.N. Morris, November 1991.

APPENDIX B

Radon Calculation

Purpose: To determine the required soil cover thicknesses to limit radon emissions from the White Mesa tailings impoundments to 20 pCi/m^2/sec using United States Nuclear Regulatory Commission (NRC) approved methods and inputs. The White Mesa Mill site is located in Blanding, Utah.

Method: Determine the geotechnical and radiological properties of the tailings and cover materials based on NRC-accepted methods and existing database values previously collected. Input parameters into the computer modeling program "RADON" to determine the radon flux values through the cover materials. A variety of scenarios adjusting cover thicknesses were run to determine the optimum thickness of cover materials to meet NRC specifications. It was assumed that the tailings located in the three cells at the White Mesa Mill site (Cells 2, 3, and 4A) have similar properties (Figure 1). Therefore, cover layer configurations as determined by the RADON model are applicable to the three tailings cells.

Results: A 2-layer uranium mill tailings cover composed of (from top to bottom) a 2-foot layer of random fill and a 1-foot compacted clay layer will meet NRC specifications. In addition to the tailings cover materials, a minimum of 3 feet of random fill will be placed between the tailings and soil cover to fill the currently existing freeboard. This 3 foot layer was included for modeling purposes since it will assist in reducing the radon flux from the tailings impoundments. This layer, however, is not considered a part of the actual soil cover. The resulting radon flux exiting the top cover layer of the tailings impoundment will be 13.6 pCi/m^2/sec (see Appendix A1 for RADON output).

As indicated in the "Effects of Freezing on Uranium Mill Tailings Covers Calculation Brief" (6/17/96), 6.8 inches of the top random fill cover layer will be effected by freeze/thaw conditions at Blanding Utah. This suggests that 6.8 inches of the top layer may not contribute to reductions of radon emanation from the tailings covers. To conservatively compensate for effects from freezing and thawing, 6.8 inches were subtracted from the top random fill cover layer. Executing the RADON model based on this cover configuration resulted in a radon flux emanation of 17.6 pCi/m^2/sec (see Appendix A2 for RADON output).

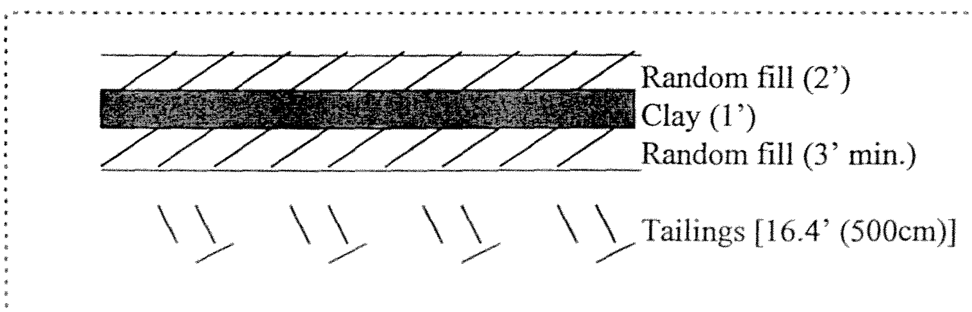
NRC specifications (Regulatory Guide 3.64) requires that a uranium tailings cover "..produce resonable assurance that the radon-222 release rate would not exceed 20 pCi/m^2/sec for a period of 1,000 years to the extent reasonably achievable and in any case for at least 200 years when averaged over the disposal area over at least a one-year period" (NRC, 1989). Therefore, the above design with accounting for freezing and thawing conditions is adequate.

Parameters: The RADON model requires input of the following parameters for all tailings and soil cover layers:

- layer thickness (centimeter (cm));
- porosity;
- mass density (g/cm^3);
- radium activity (pCi/gr), source term, or ore grade percentage;
- emanation coefficient;
- weight percent moisture (long-term) (percent), and;
- diffusion coefficient (cm^2/sec).

Physical and radiological properties for Tailings and Random Fill were analyzed by Chen and Associates (1987) and Rogers and Associates (1988) respectively. See Appendix B1 for analysis results. Clay physical data input for RADON modeling are included in Appendix B2 and were analyzed by Advanced Terra Testing (1996) and Rogers and Associates (1996).

The following cover profile was modeled.



This cover configuration represents the actual cover layer thicknesses which would be constructed on site. The cover profile above was adjusting for modeling purposes to account for freezing and thawing conditions. The modeled profile is identical to the one above with the exception of the top random fill layer which was reduced to 1.4 feet (2 feet minus 6.8 inches). It is assumed that 6.8 inches of the top cover layer effected by freeze/thaw conditions will not contribute to reductions in radon emanation from the tailings covers.

Layer thicknesses

The thickness of the tailings was assumed to be effectively an infinitely thick radon source. In accordance with NRC criteria (Reg. Guide 3.64, p. 3.64-5) a tailings thickness greater than about 100-200 cm is considered to be effectively, infinitely thick. A value of 500 cm represents an equivalent infinitely thick tailings source. The actual tailings thickness of Cell 3 at White Mesa is approximately 28 feet (850 cm), therefore, a value of 500 cm was used for the RADON model.

A minimum of 3-feet (91.5 cm) of random fill will cover the tailings to fill the existing freeboard and bring the tailings piles up to the subgrade elevation of the soil cover. A 1-foot (30.5 cm) layer of compacted clay covers the random fill with an additional 2 feet (61 cm) of random fill overlying the clay layer. Adjusting for freeze/thaw conditions results in a (43 cm) random fill layer overlaying the clay layer.

Porosity

Porosity is calculated from the specific gravity and dry bulk density according to the following equations;

1. Dry bulk density = [(specific gravity)(density of water)]/[1 + e] (Ref.: Principles & Practice of Civil Engineering, 1996, equation 14.5.6). See Appendix C.
2. Porosity = [e / (1+e)] x 100 (Ref.: Principles & Practice of Civil Engineering, 1996, equation 14.5.4). See Appendix C.

	Max. Dry Density (lb/ft^3)	Bulk Dry Density (lb/ft^3) (1)	Specific Gravity	Density of Water (lb/ft^3)	"e" (2)	**porosity (3)**
Tailings (4)	104.0	98.8	2.85	62.4	0.80	**44%**
Clay (5)	113.5	107.8	2.39	62.4	0.38	**28%**
Random fill (4)	120.2	114.2	2.67	62.4	0.46	**31.5%**

Notes:
1. Bulk dry density is 95% of the ASTM Proctor maximum dry density for all materials.
2. Calculated using Equation 1 above where "e" is the volume of voids per volume of solids.
3. Calculated using Equation 2 above.
4. Physical tailings and random fill data from Chen and Associates (1987) included in Appendix B1.
5. Clay physical data from Advanced Terra Testing (1996) and Rogers and Associates (1996) included in Appendix B2.

Mass Density

Mass densities were measured by Rogers and Associates (1988 and 1996) to be (see Appendix B1 and B2):

Tailings	= 1.45 g/cm^3
Clay	= 1.72 g/cm^3
Random Fill	= 1.85 g/cm^3

Radium Activity, Source Term, or Ore Grade %

Radium activity values from Rogers & Associates (1988 and 1996), were input for White Mesa tailings and cover materials (Appendix B1 and B2). The radium activity values are:

Tailings	= 981 pCi/gm
Clay	= 1.5 pCi/gm
Random Fill	= 1.9 pCi/gm.

Emanation Coefficient

Emanation coefficient input for the tailings and cover materials are measured values from Rogers & Associates (1988 and 1996), included in Appendix B1 and B2. The coefficients are:

Tailings	= 0.19
Clay	= 0.22
Random Fill	= 0.19

Note: Use of NRC's default value of E=0.35 is not considered appropriate since laboratory analyses of emanation coefficients are available.

Weight Percent Moisture

Long-term moisture content (weight percent moisture) was assumed to be 6% for the tailings. NRC Regulatory Guide 3.64 states, "if acceptable documented alternative information is not furnished by the applicant, the staff will use a reference value of 6% for the tailings moisture content because 6% is a lower bound for moisture in western soils" (NRC, 1989). Laboratory data does not exist to determine the actual weight percent moisture of tailings therefore, this is a conservative assumption.

The weight percent moisture of the new clay source (UT-1) is also unknown therefore, it was assumed that the average weight percent moisture from clay (site #1 and site #4) would be equivalent to the new clay source (UT-1). This is also a conservative assumption as the new clay source is believed to be of better quality. Weight percent moisture values for clay and random fill were derived from the "Summary of Capillary Moisture Relationship Test Results" figures included in Appendix B1. Weight percent moisture values used for modeling purposes are:

Tailings	= 6%
Clay	= 14.1%
Random Fill	= 9.8%

Diffusion Coefficient

Diffusion coefficient input for the tailings and cover materials are measured values from Rogers & Associates (1988 and 1996), included in Appendix B1 and B2. The coefficients used for tailings and random fill were an average of the two values presented. The coefficients for each material are as follows:

Tailings	= 0.0142 cm^2/sec
Clay	= 0.0091 cm^2/sec
Random Fill	= 0.0082 cm^2/sec

Dear Mr. Sealy:

The tests for radium content and radon emanation coefficient in the following samples have been completed and the results are as follows:

Sample	Radium (pCi/g)	Radon Emanation Coefficient
Random (2,3 & 5)	1.9 ± 0.1	0.19 ± 0.04
Site 1	2.2 ± 0.1	0.20 ± 0.03
Site 4	2.0 ± 0.1	0.11 ± 0.04

If you have any questions regarding these results please feel free to call Dr. Kirk Nielson or me.

Sincerely,

Renee Y. Bowser
Lab Supervisor

14.5 Other Useful Equations for Weight-Volume Problems

It is strongly recommended that weight-volume problems be solved using phase diagrams rather than only formulas, as completing a phase diagram clearly indicates whether sufficient information is known to complete the problem, whether information is insufficient and assumptions must be made, or whether too much information is present and the problem is overconstrained. For example, it may not be immediately apparent from the information given whether a soil is saturated until all quantities are calculated. Nevertheless, following are given additional useful equations that may be used to solve certain classes of weight-volume problems.

A very useful equation relating four different quantities is

$$Se = wG_s \tag{14.5.1}$$

For saturated soils (S = 100%) there results

$$e = wG_s \tag{14.5.2}$$

The relationships between the void ratio and porosity are

$$e = \frac{n}{1-n} \tag{14.5.3}$$

and

$$* \quad n = \frac{e}{1+e} \tag{14.5.4}$$

n = porosity
e = Volume of Voids / Volume of Solids

The total unit weight can be obtained as

$$\gamma = \frac{(G_s + Se)\gamma_w}{1+e} = \frac{(1+w)\gamma_w}{w/S + 1/G_s} \tag{14.5.5}$$

The dry unit weight can be obtained as

$$* \quad \gamma_d = \frac{G_s\gamma_w}{1+e} = \frac{G_s\gamma_w}{1+(wG_s/S)} \tag{14.5.6}$$

γ_d: Dry Bulk Density
G_s: Specific Gravity
γ_w: Density of Water

EXAMPLE 14.8

Rework example 14.6 using equations introduced in this section.

Solution.

$$Se = wG_s$$

$$S = wG_s/e = (.20)(2.65)/(0.800) = 0.6625 \text{ or } 66.3\%$$

$$n = \frac{e}{1+e} = \frac{0.800}{1+0.800} = 0.444$$

$$\gamma = \frac{(1+w)\gamma_w}{w/S + 1/G_s} = \frac{(1.20)(62.4)}{0.2/0.6625 + 1/2.65} = 110.2 \text{ lb/ft}^3$$

$$\gamma_d = \frac{G_s\gamma_w}{1+e} = \frac{(2.65)(62.4)}{1+0.800} = 91.9 \text{ lb/ft}^3$$

APPENDIX D

HELP Model

Purpose: To determine the required soil cover thicknesses to minimize surface water infiltration through the White Mesa tailings impoundments so that precipitation will not fully penetrate the soil cover. The White Mesa Mill site is located in Blanding, Utah. The performance of the tailings cover was evaluated using the Hydrologic Evaluation of Landfill Performance (HELP) Model. The HELP model was developed to facilitate rapid, economical estimation of the amounts of surface runoff, subsurface drainage, and leachate that may be expected to result from the operation of a wide variety of possible cover designs.

Method: Determine the soil properties of the cover materials and climatic properties of Blanding, Utah based on existing database values previously collected, and acceptable default parameters. Input parameters into the computer modeling program "HELP" to determine the percolation through the cover materials. A variety of scenarios adjusting cover thicknesses were run to determine the optimum thicknesses of cover materials to eliminate percolation through the bottom cover layer. The modeled tailings cover consists of a compacted clay layer over the tailings, with a random fill soil layer covering the clay.

The model was developed for Cell 3 at the White Mesa Mill since it is the largest of the three cells to be covered (Cells 2, 3, and 4A). Figure 1 shows the location of the cells. The cover requirements determined for Cell 3 will be applied to the remaining cells as well. This is a conservative approach since the remaining cells are smaller in size and require less time and distance for precipitation runoff.

Results: A two-layer uranium mill tailings cover composed of a 2-foot layer of random fill over a 1-foot compacted clay layer will reduce percolation into the tailings material to a negligible quantity (see Appendix A for HELP results). As indicated by the model results, precipitation will either runoff the soil cover or be evaporated.

The cover thicknesses recommended above were also determined to be the minimum thickness requirements for White Mesa tailings covers based on results from radon flux calculations (see "Calculation of Radon Flux from the White Mesa Tailings Cover", 9/11/96). As indicated in the Radon Flux calculation, to restrict radon flux to 20 pCi/m2/sec, (Regulatory Guide 3.64), a cover consisting of 2-feet random fill and 1-foot compacted clay is required.

Parameters: The HELP model requires input of the following parameters for the cover materials:

- Weather Data:
  - Evapotranspiration
  - Precipitation
  - Temperature
  - Solar Radiation
- Soil and Design Data:
  - Landfill area (area of Cell 3)
  - Percent of area where runoff is possible
  - Moisture content initialization
- Cover Layer Data:
  - Layer type
  - Default soil/material texture number
  - Runoff curve number

Weather Data

Evapotranspiration and *solar radiation* data was input using the default parameters from Grand Junction, Colorado. Grand Junction is located north east of Blanding Utah in a similar climate and elevation. The elevation at Grand Junction is 4,600 feet and the elevation at Blanding Utah is 5,600 feet. Figure 1 in Appendix B shows the locations of Blanding and Grand Junction in relation to one another.

Precipitation data from 1988 to 1993 (skipping 1989) was obtained from Utah State University (see Appendix C). Daily precipitation values for the five years were input manually into the HELP model. *Temperature* data was obtained from the Dames & Moore (1978) and is also included in Appendix C. Daily temperature data was not available for manual entry therefore, the computer calculated mean monthly temperatures based on the default location (Grand Junction, Colorado). These values were then edited to match the actual mean monthly temperatures for Blanding, Utah.

Soil and Design Data

The surface area of Cell 3 at the White Mesa Mill, Blanding, Utah was used for the landfill area value. The surface area, as indicated on Figure 1, is 78.7 acres. It was assumed that runoff was possible over 100% of this area and that no rain would sit on the tailings cover.

Cover Layer Data

Layer Thickness:
A two-layer cover over approximately 28 feet of uranium mill tailings was used to run the HELP model. Actual cover thicknesses which would be constructed on site consist of 2-feet of random fill over a 1-foot compacted clay layer. This cover profile was adjusted for modeling purposes to account for freezing and thawing conditions. As indicated in the "Effects of Freezing on Uranium Mill Tailings Covers Calculation Brief" (6/17/96), 6.8 inches of the top random fill cover layer will be effected by freeze/thaw conditions at Blanding, Utah. This suggests that 6.8 inches of the top layer may not contribute to reductions of infiltration into the tailings piles. To conservatively compensate for effects from freezing and thawing, 6.8 inches were subtracted from the top random fill cover layer. Therefore, modeled layer thicknesses consisted of 17.2 inches of random fill over 12 inches of clay.

Layer Type:
The random fill soil layer was classified as a vertical percolation layer. Vertical percolation layers are composed of moderate to high permeability material that drains vertically, primarily as unsaturated flow. The clay layer was classified as a barrier soil liner. This material consists of low permeability soil designed to limit percolation/leakage and drains only vertically as a saturated flow.

Moisture Storage Parameters:
Required moisture storage parameters such as; porosity, field capacity, wilting point, initial soil water content, and permeability, are interrelated with the exception of permeability. The porosity must be greater than zero but less than 1. The field capacity must be between zero and 1 but must be smaller than the porosity. The wilting point must be greater than zero but less than the field capacity, and the initial moisture content must be greater than or equal to the wilting point and less than or equal to the porosity (U.S. EPA, 1994).

Based on these relations, actual measured porosity and permeability values were input for random fill (Chen and Associates, 1987) and clay (Advanced Terra Testing, 1996, sample UT-1). See Appendix D for physical property data. In addition, wilting point data for the layers was set equal to the long-term moisture content of the materials and the soil water content was adjusted to equal the optimum moisture content. Field capacity values just less than the porosity's were assumed to maintain the interrelationship of the parameters.

Runoff Curve Number
The runoff curve number was calculated by the HELP model based on a minimum surface slope of 0.2%, slope length of 1,200 feet, soil texture of the top layer, and vegetation. A slope length of 1,200 feet was assumed to be the maximum distance which precipitation would travel over the soil cover. The top layer on the tailings cover will be minimum 3" of rock riprap (sandstone) therefore, no vegetation will exist. This top layer, however, was not included in the model to determine percolation quantities.

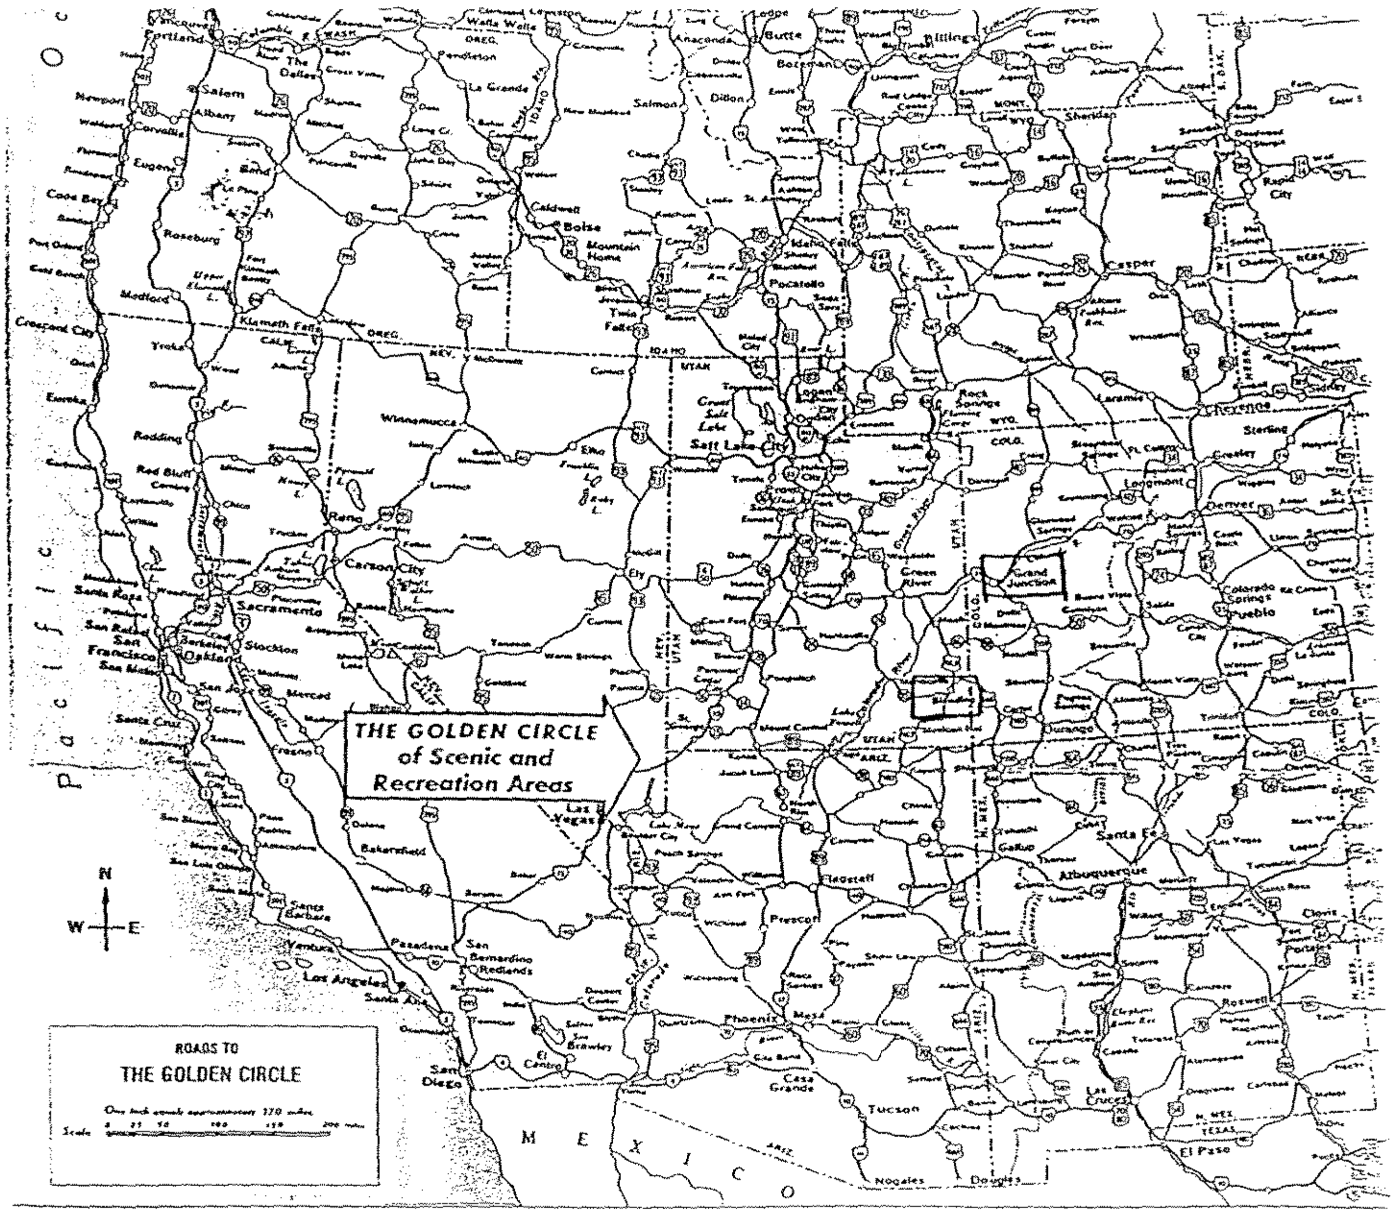
FIGURE 1
SHOWS LOCATION OF BLANDING to GRAND JUNCTION



ɜest Of The West . . .

ɪah combines the best of the West. 'ithin Utah's 85,000 square miles is a oncentrated collage of western folk-re, scenery and history.

ɛer into Utah and sample some of our ve national parks, seven national mon-ɔeats and two national recreation eas. Drive into our 43 state parks or ght national forests. Explore the ountry on this map and you'll soon cho the statement first made by pio-ɛer settlers to Utah: "This Is the Place."

IVE NATIONAL PARKS

Southeastern Utah is the place for the world's greatest—and most concen-trated—repertory of stone arches. Arches National Park's trademark is Delicate Arch, although Landscape Arch is a world record-holder with a span of 291 feet.

WHITE WATER CANYONS

The Colorado River glides past Arches and churns into Canyonlands National Park 40 miles southwest. *National Geo-graphic* labels Canyonlands "the realm of rock and far horizon. The Colorado

Eighty percent of Utah's 1.2 million people live along the foothills of the Wasatch Mountains. Salt Lake City is not only the cultural and social hub of Utah, but also the international base for the Mormon Church.

The Utah Symphony, Ballet West, Utah Repertory Dance Theater and the Pio-neer Memorial Theater all lend a cos-mopolitan atmosphere to Salt Lake City. Professional sports are represented by the Golden Eagles hockey club and the Salt Lake Gulls baseball team.

Porosity

Porosity is calculated from the specific gravity and dry bulk density according to the following equations;

1. Dry bulk density = [(specific gravity)(density of water)]/[1 + e] (Ref: Principles & Practice of Civil Engineering, 1996). See Appendix C.
2. Porosity = [e / (1+e)] x 100 (Ref: Principles & Practice of Civil Engineering, 1996). See Appendix C.

	Max. Dry Density (lb/ft^3) (1)	Dry Bulk Density (lb/ft^3) (2)	Specific Gravity (1)	Density of Water (lb/ft^3)	"e" (3)	**porosity (4)**
Tailings	104.0	93.6	2.85	62.4	0.90	47%
Clay (5)	115.0	103.5	2.72	62.4	0.64	39%
Random fill	120.2	108.2	2.67	62.4	0.54	35%

<u>Notes:</u>
1. Physical soil data from Chen and Associates (1987) included in Appendix B.
2. Bulk dry density is 90% of the ASTM Proctor maximum dry density for all materials.
3. Calculated using Equation 1 above.
4. Calculated using Equation 2 above.

Determination of Parameters (Contd.)

Permeability; No permeability data is available for tailings.

Clay material - The permeability of the clay material is an average for all clay materials near the site as given by Chen & Associates (1978, 79) as "Laboratory Permeability Test Results."

The permeability value is an average of the following values;

Permeability; 8.2×10^{-8} cm/s
6.6×10^{-8}
1.2×10^{-8}
4.0×10^{-8}
1.6×10^{-8}
2.3×10^{-8}
3.2×10^{-8}
7.8×10^{-7}
1.5×10^{-6}
} Chen & Associates (7/18/78)

(Assume permeabilities for site #1 & site #4 clays are similar)

2.1×10^{-7}
4.2×10^{-7}
1.2×10^{-7}
5.0×10^{-7}
} (1/25/79)

Ave. = 2.92×10^{-7}

Random fill - The permeability of the random fill material is an average for all sand and silt material as given by Chen & Associates (1978, 79) as "Laboratory Permeability Test Results."

The permeability is an average of the following values;

Permeability; 5.5×10^{-7}
3.4×10^{-8}
6.1×10^{-7}
} Chen & Ass. (7/18/78)

4.3×10^{-6}
3.7×10^{-7}
5.8×10^{-7}
1.1×10^{-7}
5.4×10^{-7}
} (1/23/79)

Permeability (Random fill) = Ave. = 8.87×10^{-7} cm/s

APPENDIX E

Freeze/Thaw Evaluation

Purpose: To determine if freeze/thaw conditions will impact the performance of the White Mesa uranium mill tailings cover. This calculation brief predicts the depth of frost which may be anticipated at the mill site. Only frost depth is evaluated since this would have the greatest impact on cover integrity (i.e. increasing permeability or damage by frost heave).

Method: A digital computer program of the modified Berggren equation for calculating the depth of freeze or thaw in a multi-layered soil system was used for purposes presented in this calculation. This method, used for determining the frost depth, is considered adequate for Uranium Mill Tailings Remedial Action (UMTRA) Projects by the U.S. Department of Energy for the following reasons:

- It calculates depth of frost based on a zero degrees Celsius isotherm, whereas the frozen front occurs some distance above this line.
- Extrapolation of current weather records beyond 200 years is not reliable.
- Extreme changes in temperatures for the 1,000 year design life are not anticipated based on geomorphic evidence.

Parameters for the cover materials based on accepted methods and existing database values previously collected, were input into the computer modeling program to determine the depth of frost penetration. A cover thickness of 2 feet random fill over 1 foot of compacted clay (as determined by HELP and RADON computer modeling) was used.

Assumptions: The model assumes:

- One-dimensional heat flow with the entire soil mass at its mean annual temperature prior to the start of the freezing season.
- At the start of the freezing season, the surface temperature changes suddenly from the mean annual temperature to a temperature below freezing and remains at this temperature throughout the entire freezing season.
- The effect of latent heat is considered as a heat sink at the moving frost line.
- Soil freezes at a temperature of 32 degrees Fahrenheit.

Results: The total frost penetration depth is less than 6.8 inches. Therefore, the 2-foot layer of random fill will provide adequate protection to the underlying 1-foot clay layer. See Appendix A for computer modeling results.

Parameters: The computer program requires input of the following parameters for the soil cover layers:

- freezing index (degree);
- length of season (days);
- mean annual temperature (degrees Fahrenheit);
- n-factor;
- layer thickness' (inches);
- water content (percent);
- dry unit weight (lbs/cubic foot);
- heat capacity (Btu/cubic foot-deg F);
- thermal conductivity (Btu/foot-hour-deg F), and;
- latent heat of fusion (Btu/cubic foot).

Freezing Index/Length of Season/Mean Annual Temperature

Default values from Grand Junction, Colorado were used for the freezing index and length of season. Grand Junction, Colorado was used for default parameters since it is similar in elevation and climate to Blanding Utah. An actual mean annual temperature for Blanding Utah from Dames & Moore (1978) was used for modeling purposes (see Appendix B).

N-factor

A default n-factor of 0.70 for sand and gravel surface type was used as per recommended in the freeze/thaw model guidelines (Aitken and Berg, 1968).

Soil type

Soil type was considered to be fine grained soil for both cover layers. Soil type number is 5.

Layer thickness'

The thickness of the cover materials were determined by infiltration and radon flux modeling programs to be 2 feet of random fill over 1 foot of clay. For this calculation, a single 36-inch layer was used. This was used because the random fill and clay soil have very similar properties.

Moisture Content

Optimum moisture content from Chen and Associates (1987) and Advanced Terra Testing (1996) was used for the random fill and the clay (UT-1) layer respectively. This data is included in Appendix B.

Optimum moisture content:

random fill	=11.8%
clay	=13.9%

A weighted averaged moisture content of 12.5 percent was used for this analysis.

Soil Density

Soil dry density was determined from Chen and Associates (1987) for random fill and Advanced Terra Testing (1996) for clay. The maximum dry density for the random fill was measured to be 120.2 pounds per cubic foot (pcf) and the maximum dry density for the clay was measured to be 113.5 pcf. Assuming the soil will be compacted to 95 percent of the maximum density, the weighted average bulk soil density would be 112 pcf.

Heat Capacity

Based on the nomographs presented in Aitken and Berg (1968) and included herein as Figure 1, using an average soil density of 112 pcf and an average moisture content of 12.5 percent yields a heat capacity of 30 Btu/ft^3 ° F.

Thermal Conductivity

Thermal conductivity of the soil cover was assumed to be similar to that for a dry sand. The thermal conductivity of a dry sand is reported to be 0.19 Btu/ hr. ft °F (Perry, Robert H. et al., 1984) (see Table 1).

Latent Heat

Based on the nomographs presented in Aitken and Berg (1968) and included herein as Figure 1, using an average soil density of 112 pcf and an average moisture content of 12.5 percent yields a Latent Heat of 2000 Btu/ ft^3 .

Erosion Protection

PURPOSE:

Design of Erosion Protection layer of Riprap for the Cover of Uranium Tailings

An erosion protection layer of rock riprap is required to protect the soil cover for the uranium mill tailings at Blanding, Utah. The cover is supposed to have a design life of 1000 years according to requirements set by U.S. Nuclear Regulatory Commission [Ref: "Final Staff Technical Position - Design of Erosion Protection Covers for Stabilization of Uranium Mill Tailings Sites", 1990; U.S. Nuclear Regulatory Commission (U.S.N.R.C.)]. Hence the erosion protection layer should be designed accordingly. A design for the stone size and overall riprap thickness required for erosion protection is provided in this document.

METHODOLOGY:

The design for rock riprap for protection of top and side slopes of the cover is based on the guidelines provided by the following documents:

a) "Methodologies for Evaluating Long-Term Stabilization Designs of Uranium Mill Tailings Impoundments" (NUREG/CR-4620), 1986; U.S. Nuclear Regulatory Commission

b) "Final Staff Technical Position - Design of Erosion Protection Covers for Stabilization of Uranium Mill Tailings Sites", 1990; U.S. Nuclear Regulatory Commission (U.S.N.R.C.)

c) "Development of Riprap Design Criteria by Riprap Testing in Flumes"(NUREG/CR-4651), 1987; U.S. Nuclear Regulatory Commission

The top of the cover and the side slopes will be designed separately as the side slopes are much steeper than the top of the cover. Overland flow calculations will be determined based on the guidelines set by Nuclear Regulatory Commission and the site data. The size of the riprap placed on top of the tailings cover will be determined using the Safety Factor method (NUREG/CR-4651), while the Stephenson method (NUREG/CR-4651) will be applied for those placed along the side slopes.

A: Overland Flow Calculations

The methods for overland flow calculations are same for top and side slopes of the cover. The results have been tabulated under Table 1A and 2A respectively. The formulas, methodologies and equations used for overland flow calculations are discussed in this part of the document. The calculations are based on unit width of drainage area.

Average Slope 'S' and Length of drainage basin 'L': Figure 1 shows the direction of drainage for cells 2, 3 & 4. Table 1A calculates the flow parameters by varying slopes and slope lengths of cells 2, 3 & 4. Runoff and flow calculations have been provided for slopes ranging from 0.001 to 0.008 for cells 2 and 4 and from 0.001 to 0.005 for cell 3. As the slopes are very gentle, for each cell the drainage length varies negligibly and hence has been considered constant for calculation purpose. The drainage lengths have been measured from the site map. For erosion protection design of the side slopes, a side slope of 5H:1V and the maximum value of drainage lengths for cells 2, 3 & 4 have been considered (Table 2A).

Probable Maximum Precipitation (PMP): The 1-hour local storm PMP for White Mesa is 7.76 inches (data from NOAA, 1977).

Time of Concentration of Rainfall, T_c:

$$T_c = 0.00013\frac{L^{0.77}}{S^{0.385}}\text{hours} = 0.00013\frac{L^{0.77}}{S^{0.385}} \times 60\,\text{mins}$$ (Ref: Equation 4.44 in NUREG/CR-4620)

where, S = average slope of drainage basin and L = length of drainage basin in feet
The percentage of 1-hour precipitation is obtained by interpolating from Table 2.1 of NUREG/CR-4620. The minimum value of T_c used in this table is 2.5 minutes.

% PMP: The percentage for 1-hour precipitation (PMP) is obtained by interpolating from table 2.1 of NUREG/CR-4620.

Rainfall Depth:
Precipitation Amount (inches) = % PMP × PMP = % of 1-hour precipitation × PMP (Ref: Eqn. 2.1, NUREG/CR-4620).

Precipitation intensity, 'i':
Precipitation intensity in inches/hour can be computed as (Ref: Eqn. 2.2, NUREG/CR-4620):
i = rainfall depth (inches) × [60 / {rainfall duration T_c (minute)}]

Runoff Coefficient, C: Runoff coefficient depends on climatic conditions, the type of terrain, permeability, and storage potential of the basin. Runoff Coefficient has been assumed to be 0.8 for the top of cover and the side slopes (Ref: Appendix D, section 2.4 (Example) in "Final Staff Technical Position", U.S.N.R.C.).

Unit Area, A: Area of 1-ft wide drainage basin
A = Length of drainage basin (ft.) × width (ft.) = L × 1 sq. ft. = [L×1/(43560)] Acres

Peak discharge per unit width for the drainage basin, q:
By Rational method, q = CiA, where C, i & A have their usual meanings [q in cu. ft./sec (cfs), i in inches/hour and A in acres] (Ref: Eqns. 4.42 and 4.43, NUREG/CR-4620).

Flow Concentration Factor:
From section 4.9 of NUREG/CR-4620, "...it is reasonable to assume that values between 2 and 3 are attainable with only a slight evolutionary change in cover." Thus, a flow concentration factor of 3 and 2 have been assumed for top and side slopes respectively (as the top of cover is flatter than the side slopes, it has been assumed that concentration of flow will be higher on the top than along the side slopes).

Concentrated discharge per unit width for the drainage basin, q_c:
q_c (cu. ft./sec) = q × flow concentration factor

Manning's Roughness coefficient, n:
Assumed n = 0.03 for graded loam to cobbles (Ref: table 4.2, NUREG/CR-4620)

Depth of water, D:

Depth of water in ft., $D = \left[\frac{q_c \times n}{1.486\sqrt{S}}\right]^{\frac{3}{5}}$ (Ref: Eqn. 4.46, NUREG/CR-4620), where q_c is in cu. ft./sec

Permissible Velocity:
The cover permissible velocity is between 5 to 6 ft./sec (Ref: section 4.11.3, NUREG/CR-4620)

Flow Velocity, V:
Using continuity equation,
discharge = velocity × cross-sectional area

$$\therefore q_c = V \times (D \times \text{unit width}) = V \times D \times 1$$

$$\therefore V(\text{in ft./sec}) = \frac{q_c}{D \times 1}$$

For all the calculations provided in Table 1A and 2A for top of cover and side slopes respectively, $V_{developed} < V_{permissible}$

B: Calculation for Preliminary Size (D_{50}) of Rock Riprap used for Erosion Protection

B.1 Preliminary Size (D_{50}) of Riprap along Top of Cover

According to recommendations by U.S.N.R.C. [Ref: Appendix D, section 2.2 (step 5), "Final Staff Technical Position"], recent studies have indicated that Safety Factor method is more applicable for designing rock for slopes less than 10%. The slopes along top of the cover for all the cells 2, 3 and 4 do not exceed 10%. Hence the Safety Factor method has been adopted to calculate the median diameter D_{50} of the rock particles used for riprap.

According to the Safety Factor method for determination of stone size, if the Safety Factor (S.F.) is greater than unity, the riprap is considered to be safe from failure (Ref: Section 3.4.1,"Development of Riprap Design Criteria by Riprap Testing in Flumes", NUREG/CR-4651). For calculations to determine the riprap size for top of cover, a safety factor of 1.1 has been assumed and the D_{50} corresponding to this safety factor has been computed. Table 1B tabulates the results for the safety factor method.

The equations 3.5 through 3.9 of NUREG/CR-4651 (see appendix) for Safety Factor method are provided below :

$$SF = \frac{\cos\theta \tan\phi}{\eta' \tan\phi + \sin\theta \cos\beta}$$ ....eqn. A_1 (eqn. 3.5 of NUREG/CR-4651)

$$\eta' = \eta\left[\frac{1+\sin(\lambda+\beta)}{2}\right]$$ ....eqn. B_1 (eqn. 3.6 of NUREG/CR-4651)

$$\eta = \frac{21\tau_0}{(G_s-1)\gamma_w \times D_{50}}$$ ....eqn. C_1 (eqn. 3.7 of NUREG/CR-4651)

$$\tau_0 = \gamma_w DS$$ ....eqn. D_1 (eqn. 3.8 of NUREG/CR-4651)

$$\beta = \tan^{-1}\left[\frac{\cos\lambda}{\frac{2\sin\theta}{\eta\tan\phi} + \sin\lambda}\right]$$ ....eqn. E_1 (eqn 3.9 of NUREG/CR-4651)

where,

- λ = angle between a horizontal line and the velocity vector compoment measured in the plane of side slope (refer to fig. 3.1of NUREG/CR-4651)
- θ = side slope angle
- S = side slope = tan θ
- ϕ = angle of repose (friction angle) of rock

τ_0 = bed shear stress
D_{50} = representative stone size
G_s = Specific gravity or relative density of the rock
D = depth of flow
γ_w = specific weight of the liquid (in this case, water)
η & η' = stability numbers
β = angle between vector component of the weight, Ws, directed down the side slope and the direction of particle movement

For top of the cover, as slopes are very gentle, for all practical purposes, λ can be considered to be equal to zero (Ref: pg 22, NUREG/CR-4651)

Thus for $\lambda = 0$: $\cos\lambda = 1$, $\sin\lambda = 0$.

Hence, equation 3.9 of NUREG/CR-4651 can be reduced to

$$\beta = \tan^{-1}\left[\frac{\eta\tan\phi}{2\sin\theta}\right] \text{.......eqn } E_2 \text{ (eqn 3.10 of NUREG/CR-4651)}$$

Also, equation 3.6 of NUREG/CR-4651 can be reduced to

$$\eta' = \eta\left[\frac{1+\sin\beta}{2}\right] \text{.......eqn. } B_2$$

ϕ = 40° (see Table 3)
G_s = 2.48 (see Table 3)
γ_w = 62.4 lb./ft^3

The values for depth of water 'D' have been computed in Table 1A. Table 1B provides the preliminary D_{50} size for each of cells 2, 3 & 4 by varying the slope and the length of the drainage basin.

D_{50} calculated by CSU method

According to CSU method (Ref: NUREG/CR-4651, Phase-II),

$D_{50} = 5.23 \times (\text{slope})^{0.43} \times (\text{discharge})^{0.56}$

The results of D_{50} computed by CSU method have been included in table 1B (values of discharge have been computed in table 1A to compare with those obtained by Safety Factor method.

B.2 Preliminary Size (D_{50}) of Riprap along Side Slopes

According to recommendations by U.S.N.R.C. (Ref: Appendix D, section 2.2 (step 5), "Final Staff Technical Position"), recent studies have indicated that Stephenson method is more applicable for designing rock for slopes less than 10%. As the side slopes (5H:1V) have a value of S = 1/5 = 0.2 = 20%(>10%), the Stephenson method (Ref: "Development of Riprap Design Criteria by Riprap Testing in Flumes", NUREG/ CR-4651) will be most appropriate.

By **Stephenson method**, the median size for rock, D_{50} is given by the following equation (Ref: eqn. 3.15, NUREG/CR-4651):

$$D_{50} = \left[\frac{q_c (\tan\theta)^{\frac{7}{6}} \times n_p^{\frac{1}{6}}}{C\sqrt{g} \times [(1-n_p)(G_s-1)(\cos\theta)(\tan\phi - \tan\theta)]^{\frac{5}{3}}} \right]^{\frac{2}{3}}$$

where, q_c = Concentrated discharge in cu. ft./sec
θ = Slope angle = $\tan^{-1}$ (S) = $\tan^{-1}$ (0.2) = 11.31°
ϕ = Friction angle of the rock = 40° (see Table 3)
G_s = Relative Density of the rock = 2.48 (see Table 3)
g = Acceleration due to gravity = 32.2 ft./sec^2
n_p = Porosity of the rock = 0.30 (for sandstone) [Ref: (a) "Origin of Sedimentary Rocks" and (b) Table 3
C = Empirical factor [0.22 for gravel/pebble and 0.27 for crushed granite]
Also, K = Oliver's constant [1.2 for gravel and 1.8 for crushed rock]

The results for q_c from table 2A have been substituted into the above equation and the solution tabulated in table 2B. The value of D_{50} has been multiplied by the Oliver's constant K to insure stability.

D_{50} calculated by CSU method

According to CSU method (Ref: NUREG/CR-4651, Phase-II),

$D_{50} = 5.23 \times (\text{slope})^{0.43} \times (\text{discharge})^{0.56}$

The results of D_{50} computed by CSU method have been included in table 2B to compare with those obtained by Stephenson method.

C: Oversizing of Riprap based on durability and Overall Riprap Thickness

C.1 Modification of Size (D_{50}) of Riprap based on Durability

Tables 3 and 4 include the properties of the rock to be used as protective cover material. Based on these values and according to the scoring criteria set by U.S.N.R.C. (Ref: Appendix D, sections 6.2, 6.2.1,6.2.2 and table D-1 in "Final Staff Technical Position"), a rock rating analysis has been provided in Table 4. The results show a rock rating of 55.74%, which according to U.S.N.R.C. can be used for non critical areas like top slopes and side slopes.

Thus the oversizing required = 80-55.74 = 24.26%
[ref: (a) Appendix D, section 6.2.2B, "Final Staff Technical Position"; U.S.N.R.C. (oversizing required based on a 80-rating), (b) Appendix D, section 6.4 (example), "Final Staff Technical Position" and (c) Table 4.
However a oversizing factor of 25 % has been used. Thus the nominal diameter D_{50} obtained in tables 1B and 2B has been multiplied with 1.25 to obtain a modified rock size D_{50} (tables 1C and 2C).

C.2 Overall Riprap Thickness

According to the Safety Factor method, it is recommended that the riprap thickness be at least 1.5 times the D_{50} value whereas according to the Stephenson method the riprap thickness should be at least 2 times the D_{50} value. The results based on the above recommendations are shown in tables 1C and 2C respectively.

RESULTS:

Results of the calculations have been tabulated under tables 1A, 1B, 1C, 2A, 2B, 2C respectively.

FINAL

STAFF TECHNICAL POSITION

DESIGN OF EROSION PROTECTION COVERS FOR STABILIZATION OF URANIUM MILL TAILINGS SITES

U. S. Nuclear Regulatory Commission

August 1990

FINAL
STAFF TECHNICAL POSITION
DESIGN OF EROSION PROTECTION COVERS FOR
STABILIZATION OF URANIUM MILL TAILINGS SITES

1. INTRODUCTION

Criteria and standards for environmental protection may be found in the Uranium Mill Tailings Radiation Control Act (UMTRCA) of 1978 (PL 95-604) (see Ref. 1) and 10 CFR Section 20.106, "Radioactivity in Effluents to Unrestricted Areas." In 1983, the U. S. Environmental Protection Agency (EPA) established standards (40 CFR Part 192) for the final stabilization of uranium mill tailings for inactive (Title I) and active (Title II) sites. In 1980, the United States Nuclear Regulatory Commission (NRC) promulgated regulations (10 CFR Part 40, Appendix A) for active sites and later revised Appendix A to conform to the standards in 40 CFR Part 192. These standards and regulations establish the criteria to be met in providing long-term stabilization.

These regulations also prescribe criteria for control of tailings. For the purpose of this staff technical position (STP), control of tailings is defined as providing an adequate cover to protect against exposure or erosion of the tailings. To help licensees and applicants meet Federal guidelines, this STP describes design practices the NRC staff has found acceptable for providing such protection for 200 to 1000 years and focuses principally on the design of tailings covers to provide that protection.

Presently, very little information exists on designing covers to remain effective for 1000 years. Numerous examples can be cited where covers for protection of tailings embankments and other applications have experienced significant erosion over relatively short periods (less than 50 years). Experience with reclamation of coal-mining projects, ror example, indicates that it is usually necessary to provide relatively flat slopes to maintain overall site stability (Wells and Jercinovic, 1983, see Ref. 2).

Because of the basic lack of design experience and technical information in this area, this position attempts to adapt standard hydraulic design methods and empirical data to the design of erosion protection covers. The design methods discussed here are based either on: (1) the use of documented hydraulic procedures that are generally applicable in any area of hydraulic design; or (2) the use of procedures developed by technical assistance contractors specifically for long-term stability applications.

It should be emphasized that a standard industry practice for stabilizing tailings for 1000 years does not currently exist. However, standard practice does exist for providing stable channel sections. This practice is widely used to design drainage channels that do not erode when subjected to design flood flows. Since an embankment slope can be treated as a wide channel, the staff concludes that the hydraulic design principles and practice associated with

2.1.2 Long-Term Stability

As required by 40 CFR 192.02 and 10 CFR Part 40, Appendix A, Criterion 6, stabilization designs must provide reasonable assurance of control of radiological hazards for a 1000-year period, to the extent practicable, but in any case, for a minimum 200-year period. The NRC staff has concluded that the risks from tailings could be accommodated by a design standard that requires that there be reasonable assurance that the tailings remain stable for a period of 1000 (or at least 200) years, preferably with reliance placed on passive controls (such as earth and rock covers), rather than routine maintenance.

2.1.3 Design for Minimal Maintenance

Criteria for tailings stabilization, with minimal reliance placed on active maintenance, are established in 40 CFR Part 192 and 10 CFR Part 40, Appendix A, Criteria 1 and 12. Criterion 1 of 10 CFR Part 40, Appendix A specifically states that: "Tailings should be disposed of in a manner [such] that no active maintenance is required to preserve conditions of the site." Criterion 12 states that: "The final disposition of tailings or wastes at milling sites should be such that ongoing active maintenance is not necessary to preserve isolation."

It is evident that remedial action designs are intended to last for a long time, without the need for active maintenance. Therefore, in accordance with regulatory requirements, the NRC staff has concluded that the goal of any design for long-term stabilization to meet applicable design criteria should be to provide overall site stability for very long time periods, with no reliance placed on active maintenance.

For the purposes of this STP, active maintenance is defined as any maintenance that is <u>needed</u> to assure that the design will meet specified longevity requirements. Such maintenance includes even minor maintenance, such as the addition of soil to small rills and gullies. The question that must be answered is whether longevity is dependent on the maintenance. If it is necessary to repair gullies, for example, to prevent their growth and ultimate erosion into tailings, then that maintenance is considered to be active maintenance.

2.1.4 Radon Release Limits

Titles 40 CFR 192.02 and 10 CFR Part 40, Appendix A require that earthen covers be placed over tailings at the end of milling operations to limit releases of radon-222 to not more than an average of 20 picocuries per square meter per second (pCi/m^2s), when averaged over the entire surface of the disposal site and over at least a one-year period, for the control period of 200 to 1000 years. Before placement of the cover, radon release rates are calculated in designing the protective covers and barriers for uranium mill tailings. Additionally, recent regulations promulgated under the Clean Air Act design follows the procedure for a soil cover, because the layer is predominantly soil, rather than rock.

2.2 Design Procedures

A step-by-step procedure for designing riprap for the top and side slopes of a reclaimed pile is presented below:

Step 1. Determine the drainage areas for both the top slope and the side slope. These drainage areas are normally computed on a unit-width basis.

Step 2. Determine time of concentration (tc).

The tc is usually a difficult parameter to estimate in the design of a rock layer. Based on a review of the various methods for calculating tc, the NRC staff concludes that a method such as the Kirpich method, as discussed by Nelson, et al. (1986, see Ref. D2), should be used. The tc may be calculated using the formula:

$$tc = (11.9L^3/H)^{.385}$$, where L = drainage length (in miles)

H = elevation difference (in feet)

Step 3. Determine Probable Maximum Flood (PMF) and Probable Maximum Precipitation (PMP).

Techniques for PMP determinations have been developed for the entire United States, primarily by the National Oceanographic and Atmospheric Administration, in the form of hydrometeorological reports for specific regions. These techniques are commonly accepted and provide straightforward procedures for assessing rainfall potential, with minimal variability. Acceptable methods for determining the total magnitude of the PMP and various PMP intensities for specific times of concentration are given by Nelson, et al. (1986, see Ref. D2, Section 2.1).

Step 4. Calculate peak flow rate.

The Rational Formula, as discussed by Nelson et al. (1986, see Ref. D2), may be used to calculate peak flow rates for these small drainage areas. Other methods that are more precise are also acceptable; the Rational Formula was chosen for its simplicity and ease of computation.

Step 5. Determine rock size.

Using the peak flow rate calculated in Step 4, the required D_{50} may be determined. Recent studies performed for the NRC staff (Abt, et al., 1988, see Ref. D3) have indicated that the Safety Factors Method is more applicable for designing rock for slopes less than 10 percent and that the Stephenson Method is more applicable for slopes greater than 10 percent. Other methods may also be used, if properly justified.

2.3 Recommendations

Since it is unlikely that clogging of the riprap voids will not occur over a long period of time, it is suggested that no credit be taken for flow through the riprap voids. Even if the voids become clogged, it is unlikely that stability will be affected, as indicated by tests performed for the NRC staff by Abt, et al. (1987, see Ref. D4).

If rounded rather than angular rock is used, some increase in the average rock size may be necessary, since the rock will not be as stable. Computational models, such as the Safety Factors Method, provide stability coefficients for different angles of repose of the material. The need for oversizing of rounded rock is further discussed by Abt, et al. (1987, see Ref. D4).

2.4 Example of Procedure Application

Determine the riprap requirements for a tailings pile top slope with a length of 1000 feet and a slope of 0.02 and for the side slope with an additional length of 250 feet and a slope of 0.2 (20 percent).

Step 1. The drainage areas for the top slope (A1) and the side slope (A2) on a unit-width basis are computed as follows:

$$A1 = (1000)\ (1)\ /\ 43560 = 0.023 \text{ acres}$$

$$A2 = (1000 + 250)\ (1)\ /\ 43560 = 0.029 \text{ acres.}$$

Step 2. The tcs are individually computed for the top and side slopes, using the Kirpich Method, as discussed by Nelson, et al. (1986, see Ref. D2).

$$tc = [(11.9)(L)^3/H]^{.385}$$

For L = 1000 feet and H = 20 feet,

tc = 0.12 hours = 7.2 minutes for the top slope

For L = 250 feet and H = 50 feet,

tc = 1.0 minute for the side slope.

Therefore, the total tc for the side slope is equal to 7.2 + 1.0, or 8.2 minutes.

Step 3. The rainfall intensity is determined using procedures discussed by Nelson, et al. (1986, see Ref. D2), based on a 7.2-minute PMP of 4.2 inches for the top slope and an 8.2-minute PMP of approximately 4.5 inches for the side slope. These incremental PMPs are based on a one-hour PMP of 8.0 inches for northwestern New Mexico and were derived using procedures discussed by Nelson, et al. (1986, see Ref. D2).

Rainfall intensities, for use in the Rational Formula, are computed as follows:

i_1 = (60)(4.2)/7.2 = 35 inches/hr for the top slope

i_2 = (60)(4.5)/8.2 = 33 inches/hr for the side slope.

Step 4. Assuming a runoff coefficient (C) of 0.8, the peak flow rates are calculated using the Rational Formula, as follows:

Q1 = (0.8) (35) (0.023) = 0.64 cfs/ft, for the top slope, and

Q2 = (0.8) (33) (0.029) = 0.77 cfs/ft, for the side slope.

Step 5. Using the Safety Factors Method, the required rock size for the pile top slope is calculated to be:

D_{50} = 0.6 inches.

Using the Stephenson Method, the required rock size for the side slopes is calculated to be:

D_{50} = 3.1 inches.

2.5 Limitations

The use of the aforementioned procedures is widely applicable. The Stephenson Method is an empirical approach and is not applicable to gentle slopes. The Safety Factors Method is conservative for steep slopes. Other methods may also be used, if properly justified.

3. RIPRAP DESIGN FOR DIVERSION CHANNELS

3.1 Technical Basis

The Safety Factors Method or other shear stress methods are generally accepted as reliable methods for determining riprap requirements for channels. These methods are based on a comparison of the stresses exerted by the flood flows with the allowable stress permitted by the rock. Documented methods are readily available for determining flow depths and Manning "n" values.

3.2 Design Procedures

3.2.1 Normal Channel Designs

In designing the riprap for a diversion channel where there are no particularly difficult erosion considerations, the design of the erosion protection is relatively straightforward.

1. The Safety Factors Method or other shear stress methods may be used to determine the riprap requirements.

2. The peak shear stress should be used for design purposes and can be determined by substituting the value of the depth of flow (y) in the shear

6. OVERSIZING OF MARGINAL-QUALITY EROSION PROTECTION

6.1 Technical Basis

The ability of some rock to survive without significant degradation for long time periods is well-documented by archaeological and historic evidence (Lindsey, et al., 1982, see Ref. D13). However, very little information is available to quantitatively assess the quality of rock needed to survive for long periods, based on its physical properties.

In assessing the long-term durability of erosion protection materials, the NRC staff has relied principally on the results of durability tests at several sites and on information, analyses, and methodology presented in NUREG/CR-4620 (Nelson, et al., see Ref. D2). This document provides a quantitative method for determining the oversizing requirements for a particular rock type to be placed at specific locations on or near a remediated uranium mill tailings pile.

Staff review of actual field data from several tailings sites has indicated that the methodology may not be sufficiently flexible to allow the use of "borderline" quality rock, where a particular type of rock fails to meet minimum qualifications for placement in a specific zone, but fails to qualify by only a small amount. This may be very important, since the selection of a particular rock type and rock size depends on its quality and where it will be placed on the embankment.

Based on NRC staff review of the actual field data, the methodology previously derived has been modified to incorporate additional flexibility. These revisions include modifications to the quality ratings required for use in a particular placement zone, re-classification of the placement zones, reassessment of weighting factors based on the rock type, and more detailed procedures for computing rock quality and the amount of oversizing required.

Based on an examination of the actual field performance of various types and quality of rock (Esmiol, 1967, see Ref. D14), the NRC staff considers it important to determine rock properties with a petrographic examination. The case history data indicated that the singlemost important factor in rock deterioration was the presence of smectites and expanding lattice clay minerals. Therefore, if a petrographic examination indicates the presence of such minerals, the rock will not be suitable for long-term applications.

6.2 Design Procedures

Design procedures and criteria have been developed by the NRC staff for use in selecting and evaluating rock for use as riprap to survive long time periods. The methods are considered to be flexible enough to accommodate a wide range of rock types and a wide range of rock quality for use in various long-term stability applications.

The first step in the design process is to determine the quality of the rock, based on its physical properties. The second step is to determine the amount of oversizing needed, if the rock is not of good quality. Various combinations of good-quality rock and oversized marginal-quality rock may also be considered in the design, if necessary.

6.2.1 Procedures for Assessing Rock Quality

The suitability of rock to be used as a protective cover should be assessed by laboratory tests to determine the physical characteristics of the rocks. Several durability tests should be performed to classify the rock as being of poor, fair (intermediate), or good quality. For each rock source under consideration, the quality ratings should be based on the results of about three to four different durability test methods for initial screening and about six test methods for final sizing of the rock(s) selected for inclusion in the design. Procedures for determining the rock quality and determining a rock quality "score" are developed in Table D1.

6.2.2 Oversizing Criteria

Oversizing criteria vary, depending on the location where the rock will be placed. Areas that are frequently saturated are generally more vulnerable to weathering than occasionally-saturated areas where freeze/thaw and wet/dry cycles occur less frequently. The amount of oversizing to be applied will also depend on where the rock will be placed and its importance to the overall performance of the reclamation design. For the purposes of rock oversizing, the following criteria have been developed:

A. Critical Areas. These areas include, as a minimum, frequently-saturated areas, all channels, poorly-drained toes and aprons, control structures, and energy dissipation areas.

Rating

80-100 - No Oversizing Needed

65-80 - Oversize using factor of (80-Rating), expressed as the percent increase in rock diameter. For example, a rock with a rating of 70 will require oversizing of 10 percent. (See example of procedure application, given in Section 6.4, p. D-28)

Less than 65 - Reject

B. Non-Critical Areas. These areas include occasionally-saturated areas, top slopes, side slopes, and well-drained toes and aprons.

Rating

80-100	-	No Oversizing Needed
50-80	-	Oversize using factor of (80-Rating), expressed as the percent increase in rock diameter

Less than 50 - Reject

TABLE D1

Scoring Criteria for Determining Rock Quality

Laboratory Test	Weighting Factor			Score										
	Limestone	Sandstone	Igneous	10	9	8	7	6	5	4	3	2	1	0
				Good				Fair			Poor			
Sp. Gravity	12	6	9	2.75	2.70	2.65	2.60	2.55	2.50	2.45	2.40	2.35	2.40	2.25
Absorption, %	13	5	2	.1	.3	.5	.67	.83	1.0	1.5	2.0	2.5	3.0	3.[illegible]
Sodium Sulfate, %	4	3	11	1.0	3.0	5.0	6.7	8.3	10.0	12.5	15.0	20.0	25.0	30.0
L/A Abrasion (100 revs), %	1	8	1	1.0	3.0	5.0	6.7	8.3	10.0	12.5	15.0	20.0	25.0	30.0
Schmidt Hammer	11	13	[illegible]	70.0	65.0	60.0	54.0	47.0	40.0	32.0	24.0	16.0	8.0	0.0
Tensile Strength, psi	6	4	10	1400	1200	1000	833	666	500	400	300	200	100	0

1. Scores were derived from Tables 6.2, 6.5, and 6.7 of NUREG/CR-2642 - "Long-Term Survivability of Riprap for Armoring Uranium Mill Tailings and Covers: A Literature Review," 1982 (see Ref. D13).

2. Weighting Factors are derived from Table 7 of "Petrographic Investigations of Rock Durability and Comparisons of Various Test Procedures," by G. W. DuPuy, Engineering Geology, July, 1965 (see Ref. D15). Weighting factors are based on inverse of ranking of test methods for each rock type. Other tests may be used; weighting factors for these tests may be derived using Table 7, by counting upward from the bottom of the table.

3. Test methods should be standardized, if a standard test is available and should be those used in NUREG/CR-2642 (see Ref. D13), so that proper correlations can be made. This is particularly important for the tensile strength test, where several methods may be used; the method discussed by Nilsson (1962, see Ref. D16) for tensile strength was used in the scoring procedure.

6.3 Recommendations

Based on the performance histories of various rock types and the overall intent of achieving long-term stability, the following recommendations should be considered in assessing rock quality and determining riprap requirements for a particular design.

1. The rock that is to be used should first be qualitatively rated at least "fair" in a petrographic examination conducted by a geologist or engineer experienced in petrographic analysis. See NUREG/CR-4620, Table 6.4 (see Ref. D2), for general guidance on qualitative petrographic ratings. In addition, if a rock contains smectites or expanding lattice clay minerals, it will not be acceptable.

2. An occasionally-saturated area is defined as an area with underlying filter blankets and slopes that provide good drainage and are steep enough to preclude ponding, considering differential settlement, and are located well above normal groundwater levels; otherwise, the area is classified as frequently-saturated. Natural channels and relatively flat man-made diversion channels should be classified as frequently-saturated. Generally, any toe or apron located below grade should be classified as frequently-saturated; such toes and aprons are considered to be poorly-drained in most cases.

3. Using the scoring criteria given in Table D1, the results of a durability test determines the score; this score is then multiplied by the weighting factor for the particular rock type. The final rating should be calculated as the percentage of the maximum possible score for all durability tests that were performed. See example of procedure application for additional guidance on determining final rating.

4. For final selection and oversizing, the rating may be based on the durability tests indicated in the scoring criteria. Other tests may also

be substituted or added, as appropriate, depending on rock type and site-specific factors. The durability tests given in Table D1 are not intended to be all-inclusive. They represent some of the more commonly-used tests or tests where data may be published or readily-available. Designers may wish to use other tests than those presented; such an approach is acceptable. Scoring criteria may be developed for other tests, using procedures and references recommended in Table D1. Further, if a rock type barely fails to meet minimum criteria for placement in a particular area, with proper justification and documentation, it may be feasible to throw out the results of a test that may not be particularly applicable and substitute one or more tests with higher weighting factors, depending on the rock type or site location. In such cases, consideration should be given to performing several additional tests. The additional tests should be those that are among the most applicable tests for a specific rock type, as indicated by the highest weighting factors given in the scoring criteria for that rock type.

5. The percentage increase of oversizing should be applied to the diameter of the rock.

6. The oversizing calculations represent minimum increases. Rock sizes as large as practicable should be provided. (It is assumed, for example, that a 12-inch layer of 4-inch rock costs the same as a 12-inch layer of 6-inch rock.) The thickness of the rock layer should be based on the constructability of the layer, but should be at least 1.5 x D_{50}. Thicknesses of less than 6 inches may be difficult to construct, unless the rock size is relatively small.

6.4 Example of Procedure Application

It is proposed that a sandstone rock source will be used. The rock has been rated "fair" in a petrographic examination. Representative test results are given. Compute the amount of oversizing necessary.

Using the scoring criteria in Table D1, the following ratings are computed:

Lab Test	Result	Score	Weight	Score x Weight	Max. Score
Sp. Gr.	2.61	7	6	42	60
Absorp., %	1.22	4	5	20	50
Sod. Sulf., %	6.90	6	3	18	30
L.A. Abr., %	8.70	5	8	40	80
Sch. Ham.	51	6	13	78	130
Tens. Str., psi	670	6	4	24	40
Totals				222	390

The final rating is computed to be 222/390 or 57 percent. As discussed in Section 6.2, the rock is not suitable for use in frequently-saturated areas, but is suitable for use in occasionally-saturated areas, if oversized. The oversizing needed is equal to (80 - 57), or a 23 percent increase in rock diameter.

6.5 Limitations

The procedure previously presented is intended to provide an approximate quantitative method of assessing rock quality and rock durability. Although the procedure should provide rock of reasonable quality, additional data and studies are needed to establish performance histories of rock types that have a score of a specific magnitude. It should be emphasized that the procedure is only a more quantitative estimate of rock quality, based on USBR classification standards.

It should also be recognized that durability tests are not generally intended to determine if rock will actually deteriorate enough to adversely affect the stability of a reclaimed tailings pile for a design life of 200 to 1000 years. These tests are primarily intended to determine acceptability of rock for various construction purposes for design lifetimes much shorter than 1000 years. Therefore, although higher scores give a higher degree of confidence that significant deterioration will not occur, there is not complete assurance that deterioration will not occur. Further, typical construction projects rely on planned maintenance to correct deficiencies. It follows, then, that there is also less assurance that the oversizing methodology will actually result in rock that will only deteriorate a given amount in a specified time period. The amount of oversizing resulting from these calculations is based on the engineering judgment of the NRC staff, with the assistance of contractors. However, in keeping with the Management Position (USNRC, 1989, see Ref. D17), the staff considers that this methodology will provide reasonable assurance of the effectiveness of the rock over the design lifetime of the project.

The rainfall depth for a specific site is estimated by determining the rainfall duration and/or appropriate time of concentration. The resulting rainfall depth in inches, is

$$\text{PMP rainfall depth} = (\%\ \text{PMP}) \times (\text{PMP}) \qquad (2.1)$$

where the percent PMP is obtained from Table 2.1 and the PMP is obtained from the appropriate PMP design storm presented in Section 2.1.1.

The rainfall intensity, i, in inches per hour can be computed as

$$i = \text{rainfall depth (inches)} \times \frac{60}{\text{rainfall duration (minutes)}} \qquad (2.2)$$

The rainfall intensity determined from Equation 2.2 is generally a conservative value and represents the peak rainfall intensity of the design storm.

To compute the rainfall intensity for any rainfall duration, it is recommended that a rainfall intensity versus rainfall duration curve be plotted on semilogarithmic paper. Because of the extremely conservative rainfall intensity values obtained for short durations, it is recommended that the minimum rainfall duration be 2.5 minutes. Rainfall depths should be extracted from the appropriate Hydrometeorological Report.

2.2 PMP COMPARISON STORMS

A comparison of estimates of the PMP with greatest observed rainfall and estimates of the 100-year events for areas both east and west of the 105° meridian was prepared (NWS, 1980). Information from 6500 precipitation reporting stations in the eastern U.S. and about 2100 stations in the west was used. Including storm durations of 6 to 72 hours, the study indicated that 177 separate storm events have been recorded in which the rainfall was greater than or equal to 50 percent of the PMP for stations east of the 105° meridian. Only 66 separate storm events were recorded west of the 105° meridian where rainfalls were greater than or equal to 50 percent of the PMP.

The National Weather Service also reported the number of storm events which met or exceeded the 100-year rainfall values and compared them with the regional PMP values (NWS, 1980). Table 2.2 summarizes these rainfall events for 6 and 24-hour storms occurring over a 10 square mile area. It is interesting to note that a storm has not been officially recorded west of the Continental Divide that exceeds 90% of the PMP value. However, it is evident that a number of storms approach the PMP values, thereby substantiating that the prescribed PMP values are not extremely conservative.

4.1.5.6 Gully Width

The width of the gully across the top of the gully at the point of maximum depth can be estimated from Figure 4.5. Having computed the maximum depth, D_{max}, and knowing the uniformity coefficient, C_u, the top width is estimated to be approximately 5.6 feet. However, the gully width will widen over time to where the gully side wall stands at an angle less than the angle of repose of the cover material.

4.2 EMBANKMENT AND SLOPE STABILIZATION USING RIPRAP

Rock riprap is one of the most economical materials that is commonly used to provide for cover and slope protection. Factors to consider when designing rock riprap are: (1) rock durability, density, size, shape, angularity, and angle of repose; (2) water velocity, depth, shear stress, and flow direction near the riprap; and (3) the slope of the embankment or cover to be protected. Through the proper sizing and placement of riprap on any impoundment cover, rill and gully erosion can be minimized to ensure long term stabilization.

The primary failure mechanism of concern is the removal of material from the impoundment due to shear forces developed by water flowing parallel and/or adjacent to the cover as described by Nelson et al. (1983). One purpose of the cover is to expedite the removal of precipitation and tributary waters away from the cover to minimize seepage and percolation. However, when surface waters are not properly managed, extreme erosion may result and endanger the impoundment stability. For example, slopes are often designed and constructed to develop sheet flow conditions. After many years of exposure, sheet and rill erosion, and localized settlement, the hydraulic conditions have significantly altered causing flows to merge or concentrate into drainage channels. The greater the concentration of flow into the drainage channels, the greater the erosion potential.

4.2.1 Zone Protection

The design requirements for placing riprap rock on a cover vary depending upon cover location. It is suggested that four areas exist on the cover in which different failure mechanisms can result from tributary drainage. The four areas or zones of concern are presented in Figure 4.6 and include:

1. Zone I: This zone is considered the toe-of-the-slope of the reclaimed impoundment. The riprap protecting the slope toe must be sized to stabilize the slope due to flooding in the major watersheds and dissipate energy as the flow transitions from the impoundment slope into the natural terrain. Zone I is considered a zone of frequent saturation.

2. Zone II: This is the area along the side slope which remains in the major watershed flood plain (PMF). The rock protection must resist not only the flow off the cover, but also floods. The

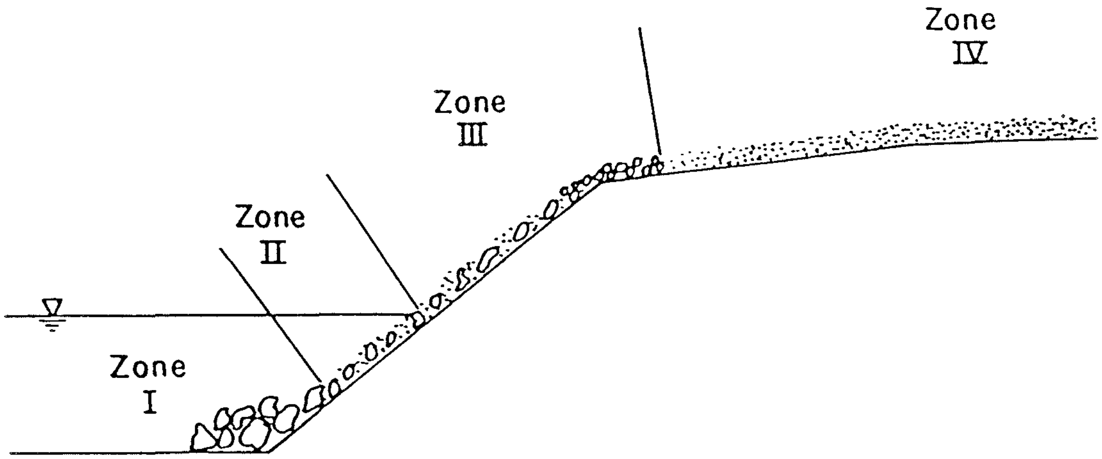

Fig. 4.6. Zones of a reclaimed impoundment requiring riprap protection.

riprap must serve as embankment protection similar to river and canal banks. Zone II is considered a zone of occasional saturation.

3. Zone III: Riprap should be designed to protect steep slopes and embankments from potential high overtopping velocities and excessive erosion. Flows in Zone III are derived from tributary drainage and direct runoff from the reclaimed site. Zone III is considered a seldom saturated zone.

4. Zone IV: Rock protection for Zone IV is generally designed for flows from mild slopes. Zone IV will usually be characterized by sheet flow with low flow velocities. Zone IV is considered a zone of seldom saturation.

Since the rock protection requirements are significantly different on various locations on the cover, it should be apparent that each riprap design procedure available was formulated to address a specific application. Since a single riprap design procedure does not necessarily meet all of the cover protection requirements, recommendations will be made indicating which zone(s) each riprap design procedure best addresses.

Because the frequency of wetting or saturation varies by zone, the durability requirements of the riprap may vary by zone. The concept of durability and oversizing will be addressed in Chapter 6 of this report.

4.2.2 Design Procedures

Presently, several methods are available to assist the designer in determining the appropriate rock size for protection of impoundment covers, embankments and unprotected slopes from the impact of drainage waters. Alternative riprap design methods summarized herein are

1. Safety Factors Method
2. The Stephenson Method
3. Corps of Engineers Method
4. The U.S. Bureau of Reclamation Method

These riprap design procedures are but examples of the many methods available.

4.2.2.1 Safety Factors Method

The Safety Factors Method (Richardson et al., 1975) for sizing rock riprap is quite versatile in that it allows the designer to evaluate rock stability from flow parallel to the cover and adjacent to the cover. The Safety Factors Method can be used by assuming a rock size and then calculating the safety factor (S.F.) or allowing the designer to determine a S.F. and then computing the corresponding rock size. If the S.F. is greater than unity, the riprap is considered safe from failure; if the S.F. is unity, the rock is at the condition of incipient motion; and if S.F. is less than unity, the riprap will fail.

where d_{50} is the mean rock size in feet. A graphical representation for determining n is presented in Figures 4.12 and 4.13. However, these values were developed for uniform flow condition over submerged riprap. When overtopping flows on steep slopes begin to cascade, n values will increase and may range from 0.07 to 0.09 or higher. (Abt and Ruff, 1985 and COE, 1970).

Table 4.2. Manning Coefficient, n.

Channel Material	Manning Coefficient, n
Fine sand, colloidal	0.020
Sandy loam, non-colloidal	0.020
Silt loam, non-colloidal	0.020
Alluvial silts, non-colloidal	0.020
Ordinary firm loam	0.020
Volcanic ash	0.020
Stiff clay, very colloidal	0.025
Alluvial silts, colloidal	0.025
Shales and hardpans	0.025
Fine gravel	0.020
Graded loam to cobbles, non-colloidal	0.030
Graded silts to cobbles, colloidal	0.030
Coarse gravel, non-colloidal	0.025
Cobbles and shingles	0.035

4.8 COVER EROSION RESISTANCE EVALUATION

The cover design should be evaluated to determine if the unprotected slopes(s) can withstand overland or sheet flow with a minimum of erosion. Based upon the site-specific cover and precipitation parameters, the design sheet flow velocity should be estimated. A comparison of the design flow velocity with the cover permissible flow velocity can be performed. Furthermore, the design velocity can be used to determine the sediment discharge using the Universal Soil Loss Equation (Chapter 5) and for sizing stone protection (Section 4.2).

The design velocity will usually be determined from the peak discharge generated from the Probable Maximum Flood (PMF). The PMF can be estimated by

(a) Using computer models, i.e., HEC-1 (COE, 1974), that are widely accepted by the engineering profession.

(b) Applying the Rational Method for tributary areas that are less than approximately one square mile in area.

The Rational formula is commonly expressed as

$$Q = CiA \tag{4.42}$$

where Q is the maximum or design discharge in cfs, C is a runoff coefficient dependent upon the characterization of the drainage basin, i is the rainfall intensity expressed in inches per hour and A is the tributary area expressed in acres. When a unit width approach is taken, the area A_W is the slope(s) length times the unit width. Therefore, Equation 4.42 would be presented as

$$q = CiA_W \tag{4.43}$$

for a unit width analysis.

4.8.1 Runoff Coefficient

The runoff coefficient, C, is related to the climatic conditions and type of terrain characteristic of the watershed including soil materials, permeability and storage potential. Values of the coefficient C are presented in Table 4.4 (Lindsley et al., 1958), Table 4.5 (Chow, 1964), and Table 4.6 (ASCE, 1970 and Seelye, 1960).

Table 4.4. Values of Coefficient C.

Type Area	Value of C
Flat cultivated land, open sandy soil	0.20
Rolling cultivated land, clay-loam soil	0.50
Hill land, forested, clay loam soil	0.50
Steep, impervious slope	0.95

Source: Lindsley, et al, 1958.

The selection of a coefficient value requires considerable judgment as it is a tangible aspect of using the rational formula. It is recommended that a conservative value of C be applied for PMF estimation since infiltration and storage comprise a low percentage of the runoff. Furthermore, the C values presented were derived for storms of 5-100 year frequencies. Therefore, less frequent, higher intensity storms will require the use of a higher C value (Chow, 1964). It is recommended that a runoff coefficient of 1.0 be used for PMF applications in very small watersheds since the effects of localized storage and infiltration will be small.

Table 4.5. Values of C for Use in Rational Formula.

Soil Type	Watershed Cover		
	Cultivated	Pasture	Woodlands
With above-average infiltration rates; usually sandy or gravelly	0.20	0.15	0.10
With average infiltration rates; no clay pans; loams and similar soils	0.40	0.35	0.30
With below-average infiltration rates; heavy clay soils or soils with a clay pan near the surface; shallow soils above impervious rock	0.50	0.45	0.40

Source: Chow, 1964.

4.8.2 Rainfall Intensity

In order to determine the rainfall intensity, i, the time of concentration, t, must be estimated. The time of concentration can be approximated by:

(a) Applying one of the many accepted empirical formulae such as

$$t_c = 0.00013 \frac{L^{0.77}}{S^{0.385}} \qquad (4.44)$$

where L is the length of the basin in feet measured along the watercourse from the upper end of the watercourse to the drainage basin outlet and S is the average slope of the basin. Time of concentration is expressed in hours. This procedure is not applicable to rock covered slopes. This expression was

Table 4.6. Values of runoff coefficient C.

Character of Surface	Runoff Coefficients	
	Range	Recommended
Pavement--asphalt or concrete	0.70-0.95	0.90

designed for and applicable to small drainage basins (Kirpich, 1940).

(b) Using the Soil Conservation Service (SCS) Triangular Hydrograph Theory (DOI, 1977), the time of concentration is

$$t_c = \left(\frac{11.9\ L^3}{H}\right)^{0.385} \qquad (4.45)$$

0.385 — see USNRC (pg D-3) "Final Staff Technical Position Design of Erosion Protection Covers for Stabilization of Uranium Mill Tailings Sites" (1990)

where L is the length (miles) of the longest watercourse from the point of interest to the tributary divide, H is the difference in elevation (feet) between the point of interest and the tributary divide. The time of concentration will be expressed in hours. The SCS procedure is most applicable to drainage basins of at least 10 square miles.

Once the rainfall duration or time of concentration is determined, the rainfall depth can be computed based on the PMP intensity values estimated in Section 2.1.2.

4.8.3 Tributary Area

The tributary area may be expressed in a unit width format for design of rock protection on an embankment. Therefore, the area is the length of the longest expected or measured water course multiplied by the unit width. This procedure is primarily applicable to Zones I, II, and III and is not applicable for drainage ditch design. It should be noted that a unit width approach to drainage and diversion ditch design is not effective. Ditch design requires an entire basin analysis in which a composite inflow hydrograph is determined and is routed along the channel. From the inflow hydrograph, water surface profiles (i.e., HEC-2) can be estimated to determine flow depth and velocities for riprap design (COE, 1982).

4.8.4 Sheet Flow Velocity

The design velocity for sheet flow on an embankment slope can be estimated by solving the Manning formula presented in Equation 4.39. It is assumed that the hydraulic radius, R, is approximately equal to the flow depth, y, and that the design discharge is equal to that estimated by the Rational Method. Therefore, the depth of flow is

$$y = \left[\frac{Qn}{1.486\ S^{1/2}}\right]^{3/5} \qquad (4.46)$$

where Q is the discharge, S is the slope, and n is the Manning coefficient.

Therefore, the design velocity can be estimated as

$$V_{Design} = Q/A \text{ (feet/sec)} \qquad (4.47)$$

where A is the cross-sectional area of flow.

4.9 FLOW CONCENTRATIONS

Despite the extensive efforts of the impoundment reclamation designer, reviewer, contractor and inspector, the topographic features of the cover will alter over time without continual maintenance (Powledge and Dodge, 1985). Cover modifications will result from differential settlement, collapsing soils, marginal quality control in cover placement, erosion, major hydrologic events and monitoring disturbance. Because of these unpredictable and generally uncontrollable events, tributary drainage areas evolve that were not originally designed or constructed. The result is that the peak discharge and volume of runoff exceed design levels and increase the erosion potential.

Abt and Ruff (1985) conducted a series of flume experiments on a 1V:5H prototype embankment protected by riprap with median rock sizes of 2 inches to 6 inches in diameter. It was observd that 2-4 inch diameter riprap were highly susceptible to sheet flows converging along the face of the embankment into channels. The discharge in the channel(s) was compared to the total discharge over the embankment by

$$CF = \frac{1}{1 - (Q_c - Q)} \qquad (4.48)$$

where CF is the concentration factor, Q_c is the discharge in the channel and Q is the total discharge over the embankment. The concentration factors ranged from 1.1 to 3.2 where flows were less than the failure discharge. These preliminary results indicate that riprap designed for sheet flow conditions may be subjected to flow channelizations that concentrate 3 times the discharge in a single location.

The peak discharge along a crest or at a design point is a function of the amount of precipitation, the tributary drainage area, the slope of the drainage basin, the basin contouring, the cover material and cover protection. Any modification in one or more of these parameters can impact the outlet peak discharge. The cover design must account for these potential changes in the form of a concentration or safety factor. Therefore, a flow concentration factor may be incorporated into the design process to adequately evaluate the soil resistance to erosion, to adequately select and evaluate alternative protective measures and to size riprap when warranted.

It is difficult to accurately predict the value of the flow concentration factor since limited information is currently available to substantiate design limits. However, it is reasonable to assume that values between 2 and 3 are attainable with only a slight evolutionary change in cover. Unless it can be shown that design procedures such as overbuilding can compensate for differential settlement, it is recommended that a conservative concentration factor be used until additional research can justify a more reasonable range of values.

To incorporate the flow concentration factor into the stone sizing procedure of any riprap design method, multiply the design peak discharge by the flow concentration factor. All subsequent computations, i.e., velocity and depth estimate, stone size determination, etc., will reflect the influence of the flow concentration.

4.10 PERMISSIBLE VELOCITIES

Evaluation of proposed reclamation alternatives should include an analysis of the critical erosion potential of the cover material. Erosion potential can be determined based upon the properties of the reclamation materials as well as the degree of compaction in which the material is placed. The permissible velocity approach consists of specifying a velocity criterion that will not erode the cover or channel and will prevent scour. A comparison of the actual or design flow velocities to the permissible velocities associated with overland flows, sheetflows or channel flows determines the erosion potential. When the design flow velocity meets or exceeds the permissible velocity, cover protection should be considered.

The permissible velocity values presented were developed from experiments performed primarily in canals and stream beds. Therefore, the following permissible velocities should provide a conservative estimate for evaluating the erosion resistance of the reclaimed covers over long term periods. In cases where a range of permissible velocities are presented, it is recommended that the lower velocity be used for determining erosion potential.

A series of permissible maximum canal velocities was developed by Fortier and Scobey (1926) and adapted by Lane (1955). The maximum permissible velocities presented in Table 4.7 are applicable to colloidal silts. These velocity values were developed for channels without sinuosity. Lane recommended a reduction of the velocities in Table 4.7 by 13 percent if the canal/channel is moderately sinuous. The maximum allowable velocities for sandy-based materials are given in Table 4.8. Table 4.9 provides limiting velocities for cohesive materials according to compactness for materials with less than 50 percent sand content. The Soil Conservation Service maximum permissible velocities (SCS, 1984) for well maintained grass covers are presented in Table 4.10.

It is important to recognize that limited information is available pertaining to permissible velocities on covers under sheet flow conditions.

Table 4.7. Maximum permissible velocities in erodible channels.

Channel Material	Water Transporting Colloidal Silts v (ft/sec)
Fine sand, colloidal	2.50
Sandy loam, non-colloidal	2.50
Silty loam, non-colloidal	3.00
Alluvial silts, non-colloidal	3.50
Firm loam	3.50
Volcanic ash	3.50
Stiff clay, colloidal	5.00
Alluvial silts, colloidal	5.00
Shales and hardpans	6.00
Fine gravel	5.00
Graded loam to cobbles, non-colloidal	5.00
Graded silts to cobble, colloidal	5.50
Coarse gravel, non-colloidal	6.00
Cobbles and shingles	5.50

Source: Lane 1955.

Table 4.8. Maximum allowable velocities in sand-based material.

Material	Velocity (ft/sec)
Very light sand of quicksand character	0.75 to 1.00
Very light loose sand	1.00 to 1.50
Coarse sand to light sandy soil	1.50 to 2.00
Sandy soil	2.00 to 2.50
Sandy loam	2.50 to 2.75
Average loam, alluvial soil, volcanic ash	2.75 to 3.00
Firm loam, clay loam	3.00 to 3.75
Stiff clay soil, gravel soil	4.00 to 5.00
Coarse gravel, cobbles and shingles	5.00 to 6.00
Conglomerate, cemented gravel, soft slate, tough hardpan, soft sedimentary rock	6.00 to 8.00

Source: Lane, 1955.

Therefore, the permissible velocities developed for channels is usually extended to overland flow situations. When design velocities reach or exceed those indicated in Tables 4.7 through 4.10, protection is warranted.

Table 4.9. Limiting Velocities in Cohesive Materials.

Principle Cohesive Material	Compactness of Bed: Loose Velocity (ft/sec)	Fairly Compact Velocity (ft/sec)	Compact Velocity (ft/sec)	Very Compact Velocity (ft/sec)
Sandy clay	1.48	2.95	4.26	5.90
Heavy clayey soils	1.31	2.79	4.10	5.58
Clays	1.15	2.62	3.94	5.41
Lean clayey soils	1.05	2.30	3.44	4.43

Source: Lane, 1955.

The materials presented in Tables 4.7 through 4.9 can be referenced to the Unified Soil Classification System as presented by Wagner (1957). An engineering analysis of the cover material can provide an approximation of the permissible velocities that the alternative cover materials may withstand without supplemental protection.

4.11 PERMISSIBLE VELOCITY EXAMPLE

A tailings disposal site located in the northwest corner of New Mexico has prepared a reclamation plan for review. The reclamation plan indicates that a 10 foot thick cap will be placed atop the tailings at a slope of 2.4% with a compaction of 95% of optimum. The cap will be graded as shown in Figure 4.14 and shall transition into side slopes of 1V:10H. It is proposed that the cap will be composed of a sandy clay with a coarse gravel cover. Along the crest, a 12 inch thick layer of riprap will be placed for at least 8 feet upslope and downslope of the crest to stabilize the transition. The riprap will have a median stone size of 6 inches. The gravel cover will have a median rock size of 1.5 inches. The design reviewer must verify that the gravel cover will resist the potential velocities that may result on the cap.

In order to assess the stabilization of the cap against erosion due to overland flow, information provided in Sections 4.6 through 4.10 of this report must be utilized. One alternative means of reviewing the design is presented in the following analysis.

4.11.1 Estimation of Peak Runoff

The peak runoff can be estimated using the Rational formula presented in Equation 4.43. The three components of the Rational formula that require consideration are: the runoff coefficient, C; the rainfall intensity, i; and the tributary area, A.

The runoff coefficient can be estimated by examining Tables 4.4 through 4.6. Since the cap will be composed of a compacted clay, the infiltration and localized storage will be low. The peak runoff is a direct function of the estimated localized PMF. Therefore, a reasonable C value is 1.0.

The rainfall intensity can be estimated by determining the 1-hr, 1-mi^2 local storm PMP value and adjusting the rainfall depth in accordance with the percentages presented in Table 2.1. For northwest New Mexico, the 1-hr, 1-mi^2 PMP is estimated to be 9.5 inches after the appropriate elevation and area adjustments are performed.

The time of concentration, t_c, should be estimated. Using Equation 4.44, the t_c can be estimated where the longest flow path is approximately 450 feet as

$$t_c = 0.00013 \frac{(450)^{0.77}}{(0.024)^{0.385}} \tag{4.49}$$

and

$$t_c = 0.06 \text{ hrs} = 3.62 \text{ minutes} \tag{4.50}$$

The rainfall depth for variable rainfall durations can be estimated using the values presented in Table 2.1 which are applicable to northwest New Mexico. Since the time of concentration is 3.6 minutes, the percent of the 1-hr PMP can be interpolated to be approximately 35 percent. The rainfall depth is computed using Equation 2.1 to be

$$\text{Rainfall depth} = (0.35) \times 9.5 \text{ inch} = 3.33 \text{ inches} \tag{4.51}$$

A conservative estimate of the rainfall intensity is determined by applying Equation 2.2.

$$i = 3.33 \text{ inches} \times \frac{60}{3.6} = 55.5 \text{ inches/hr} \qquad (4.52)$$

The tributary area, A, can be estimated using a unit width approach presented in Section 4.8. Since the longest flow path is 450 feet with a unit width of one foot, the tributary area is 450 square feet. The tributary area can be converted to acres by dividing by 43,560 square feet/acre resulting in an area of 0.0103 acres.

The peak sheet flow unit discharge at the transition can be computed by using the Rational formula presented in Equation 4.43.

$$q = (1.0)\ (55.5)\ (0.0103) = 0.57 \text{ cfs} \qquad (4.53)$$

4.11.2 Sheet Flow Velocity

The sheet flow design velocity can be estimated by first determining the depth of flow. The depth of flow, y, can be calculated using Equation 4.46. However, the Manning surface roughness coefficient, n, must be determined. From Equation 4.41, the Manning n value can be calculated as

$$n = 0.0395 (d_{50})^{1/6}$$

$$n = 0.0395\ (0.125)^{1/6} = 0.028 \qquad (4.54)$$

The depth of flow is then computed to be

$$y = \left[\frac{(0.57)\ 0.028}{1.486\ (0.024)^{1/2}}\right]^{3/5} = 0.202 \text{ feet} \qquad (4.55)$$

or

$$y = (0.202 \text{ ft})\ (12 \text{ in/ft}) = 2.42 \text{ inches} \qquad (4.56)$$

The design sheet flow velocity is calculated using Equation 4.47.

$$V = \frac{0.57}{(1.0)(0.20)} = 2.82 \text{ feet/sec} \qquad (4.57)$$

where 0.57 is the unit discharge, 1.0 is the width of flow in feet and 0.20 is the depth of flow in feet. It should be noted that the flow concentration factor was not incorporated into this computation.

4.11.3 Cover Permissible Velocity

The permissible velocity for the clay cap covered with gravel has been determined to be 5.0-6.0 feet/sec as presented in Table 4.8. Since the design sheet flow velocity was calculated to be 2.9 feet/sec, the cover should be able to withstand the design flow.

embankments, channel and unprotected slopes from the impact of flowing waters. Four riprap design procedures which will be referenced are:

1. Safety Factors Method (SF)
2. The Stephenson Method (STEPH)
3. The U.S. Army Corps of Engineers Method (COE)
4. The U.S. Bureau of Reclamation Method (USBR)

A summary of each method will be presented.

3.4.1 Safety Factors Method

The Safety Factors Method (Richardson et al., 1975) for sizing riprap allows the designer to evaluate rock stability from flow parallel to the cover and adjacent to the cover. The Safety Factors Method can be used by assuming a stone size and then calculating the safety factor (SF) or allowing the designer to determine a SF and then computing the corresponding stone size. If the SF is greater than unity, the riprap is considered safe from failure; if the SF is unity, the rock is at the condition of incipient motion; and if SF is less than unity, the riprap will fail.

The following equations are provided for riprap placed on a side slope or embankment where the flow has a non-horizontal (downslope) velocity vector. The safety factor, SF, is:

$$SF = \frac{\cos\theta \tan\phi}{\eta' \tan\phi + \sin\theta \cos\beta} \tag{3.5}$$

where

$$\eta' = \eta \left[\frac{[1 + \sin(\lambda + \beta)]}{2} \right] \tag{3.6}$$

$$\eta = \frac{21\ \tau_0}{(G_s - 1)\ \gamma\ D_{50}} \tag{3.7}$$

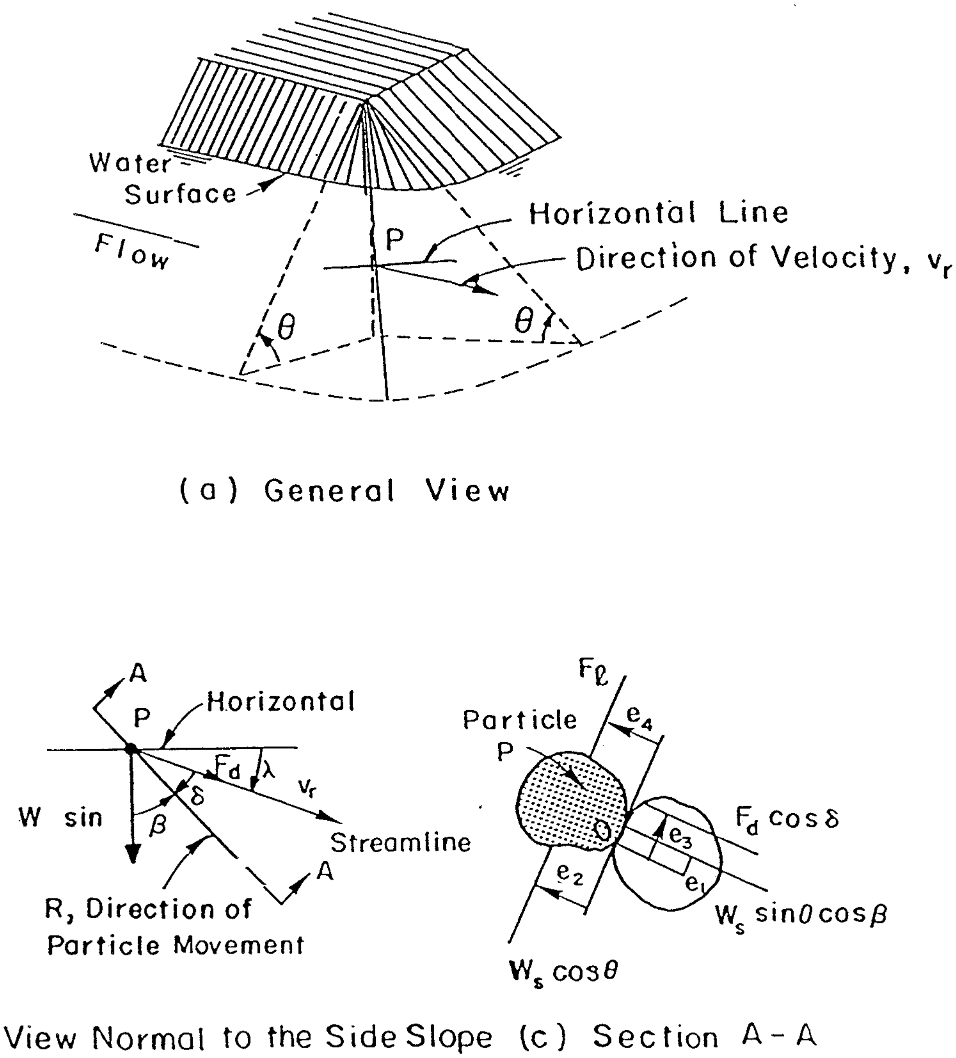
$$\tau_0 = \gamma\ DS \tag{3.8}$$

and

$$\beta = \tan^{-1} \left[\frac{\cos\lambda}{(2\ \sin\theta)/(\eta \tan\phi) + \sin\lambda} \right] \tag{3.9}$$

The angle, λ, is shown in Figure 3.1 and is the angle between a horizontal line and the velocity vector component measured in the plane of the side slope. The angle, θ, is the side slope angle shown in Figure 3.1 and β is the angle between the vector component of the weight, W_s, directed down the side slope and the direction of particle movement. The angle, ϕ, is the angle of repose of the riprap, τ_0 is the bed shear stress (Simons and Senturk, 1977), D_{50} is the representative stone size, G_s is the specific gravity of the rock, D is the depth of flow, γ is the specific weight of the liquid, S is the slope of the channel, and η' and η are stability numbers. In Figure 3.1, the forces F_l and F_d are the lift and drag forces, and the moment arms of the various forces are indicated by the value e_i as i = 1 through 4. Figure 3.2 illustrates the angle of repose for riprap material sizes.

Riprap is often placed along side slopes where the flow direction is close to horizontal or the angularity of the velocity component with the



(a) General View

(b) View Normal to the Side Slope (c) Section A - A

Fig. 3.1. Riprap stability conditions as described in the Safety Factors Method.

horizontal is small (i.e., $\lambda = 0$). For this case, the above equations reduce to:

$$\tan \beta = \frac{\eta \tan \phi}{2 \sin \theta} \tag{3.10}$$

and

$$\eta = \left[\frac{S_m^2 - (SF)^2}{(SF)\ (S_m^2)} \right] \cos \theta \tag{3.11}$$

where

$$S_m = \frac{\tan \phi}{\tan \theta} \tag{3.12}$$

The term S_m is the safety factor of the rock particles against rolling down the slope with no flow. The safety factor, SF, for horizontal flow may be expressed as:

$$SF = \frac{S_m}{2} [S_m^2 \eta^2 \sec^2 \theta + 4)^{0.5} - S_m \eta \sec \theta] \tag{3.13}$$

Riprap may also be placed on the cover or side slope. For a cover sloping in the downstream direction at an angle, α, with the horizontal, the equations reduce to:

$$SF = \frac{\cos \alpha \tan \phi}{\eta \tan \phi \sin \alpha} \tag{3.14}$$

Historic use of the Safety Factors Method has indicated that a minimum SF of 1.5 for non-PMF applications (i.e. 100-year events) provides a side slope with reliable stability and protection (Simons and Senturk, 1977). However, a SF of slightly greater than 1.0 is recommended for PMF or maximum credible flood circumstances. It is recommended that the riprap thickness be a minimum of 1.5 times the D_{50}. Also, a bedding or filter layer should underlay the rock riprap. The filter layer should minimally range from 6 inches to 12 inches in thickness. In cases where the Safety Factors Method is used to design riprap along embankments or slopes steeper than 4H:1V, it is recommended that the toe be firmly stabilized.

3.4.2 Stephenson Method

The Stephenson Method for sizing rockfill to stabilize slopes and embankments is an empirically derived procedure developed for emerging flows (Stephenson, 1979). The procedure is applicable to a relatively even layer of rockfill acting as a resistance to through and surface flow. It is ideally suited for the design and/or evaluation of embankment gradients and rockfill protection for flows parallel to the embankments, cover or slope.

The sizing of the stable stone or rock requires the designer to determine the maximum flow rate per unit width (q), the rockfill porosity (n_p), the acceleration of gravity (g), the relative density of the rock (G_s), the angle of the slope measured from the horizontal (θ), the angle of friction (ϕ), and the empirical factor (C).

The stone or rock size, D_{50}, is expressed by Stephenson as

$$D_{50} = \left[\frac{q(\tan\theta)^{7/6} n_p^{1/6}}{C\, g^{1/2}\, [1-n_p)(G_s-1)\cos\theta\,(\tan\phi - \tan\theta)]^{5/3}} \right]^{2/3} \qquad (3.15)$$

where the factor C varies from 0.22 for gravel and pebbles to 0.27 for crushed granite. The stone size calculated in Equation 3.15 is the representative diameter, D_{50}, at which rock movement is expected for unit discharge, q. The representative median stone diameter (D_{50}), is then multiplied by Oliviers' constant, K, to insure stability. Oliviers' constants are 1.2 for gravel and 1.8 for crushed rock. The rockfill layer should be well graded and at least two times the D_{50} in thickness. A bedding layer or filter should be placed under the rockfill.

The Stephenson Method does not account for uplift of the stones due to emerging flow. This procedure was developed for flow over and through rockfill on steep slopes. Therefore, it is recommended that the Stephenson Method be applied as an embankment stabilization for overflow or sheetflow conditions. Alternative riprap rockfill design procedures should be considered for toe and stream bank stabilization.

3.4.3 U.S. Army Corps of Engineers Method

The U.S. Army Corps of Engineers has developed perhaps the most comprehensive methods and procedures for sizing riprap revetment. Their criteria are based on extensive field experience and practice (COE, 1970 and

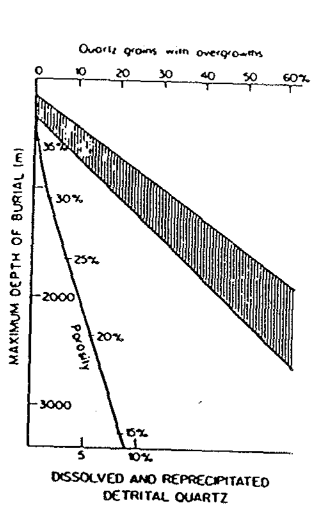

Fig. 12-8 Porosity, burial depth, and abundance of quartz overgrowths in quartz sandstones from the "Dogger beta" (Jurassic), West Germany. For example, at a depth of 1000 m the porosity is 31%, quartz overgrowths form 1% of the rock, and between 19% and 30% of the detrital quartz grains have overgrowths. (From Hans Füchtbauer, 1967, *Proc. 7th World Pet. Cong., Mexico City*, 2, 354. Used by permission of the Elsevier Scientific Pub. Co.)

by retarding pressure solution and the formation of quartz overgrowths. Fluid flow through sandstones may also enhance porosity by dissolving earlier-formed cements or detrital mineral grains.

12.4 PERMEABILITY

Permeability is a measure of the ease with which a fluid flows through a rock. It is defined by an empirical relationship first recognized by the French hydrologist Henri Darcy in 1856 and may be written

$$V = \frac{Q}{A} = k\frac{\Delta p}{\mu l}$$

where V = apparent velocity (cm/s)
Q = discharge (cm^3/s)
A = cross-sectional area (cm^2)
k = permeability (darcies = $cm^2 \times 10^{-8}$)
μ = fluid viscosity (centipoises, gm/cm s $\times 10^{-2}$)
l = distance of flow (cm)
p = pressure (dynes/cm^2); this term consists of both a fluid pressure term and a gravitational acceleration term.

Permeabilities to water of more than 500 darcies have been measured in modern river sands; in ancient rocks permeabilities to air range from a high of several darcies in coarser sandstones to a measured low of 10^{-11} darcy in a shale. The median permeability of petroleum reservoirs is on the order of 0.1 darcy (100 md).

Permeability is normally determined in the laboratory by sealing the side of the cylindrical rock core, removing any oil in the core with a solvent, and forcing air longitudinally through the core. Thus permeabilities ordinarily reported in core analysis refer to the permeability to dry air at atmospheric pressure. The permeability to freshwater, brine, or petroleum may be much less, depending on the mineral composition of the rock, particularly the amount and type of clay minerals it contains (see below). Unfortunately, the accuracy of core analysis for determining permeability is somewhat illusory. When a core is removed from the subsurface, all confining forces are removed and the rock matrix expands in all directions, partially changing the pore radii and fluid flow paths inside the core. Increases in permeability of more than 100% have been documented (Fatt and Davis, 1952). Presumably the percentage increase depends largely on the depth at which the core was taken and on the mineral composition of the core, particularly its content of clay and mica.

Subsurface measurements of permeability can be made by using semiempirical electric logging techniques, but errors of 100% are possible. A better method in use in petroliferous rocks is to determine the output of a well under a known pressure drawdown or to interpret pressure buildup data during a drill-stem test. The drill-stem test has the advantage that it represents the effective permeability of a large volume of rock under *in situ* conditions.

Depositional permeability is greatest in a direction either parallel to the bedding or at a small angle to it because of grain orientations, micaceous foliations produced during deposition of the sediment, and vertical changes in grain size within the rock unit. Johnson and Hughes (1948) examined 33 Devonian oil sands in New York and Pennsylvania and found variations in permeability averaging 30% in the plane of the bedding, with differences being less pronounced in sands of higher permeabilities. Griffiths (1949) observed that sand grains are normally imbricated at a low angle to the bedding and, therefore, planes parallel to the bedding are projections of sections through the individual grains on a plane that lies at varying angles to varying imbrications. Small variations in grain shape would result in large differences on the projection plane. He found greatest permeabilities in three cores at a low angle to the bedding and attributed the result to the existence of grain imbrication in the sandstones. Mast and Potter (1963) studied permeabilities in the bedding plane of 13 Carboniferous sandstones and concluded that variations in permeability as a result of fabric "are extremely small." Clearly it is difficult to generalize about directional permeability beyond the statement that it is least in a direction approximately normal to bedding.

In some units, however, jointing or microfaulting can increase permeability perpendicular to bedding by orders of magnitude (Nelson and Handin, 1977).

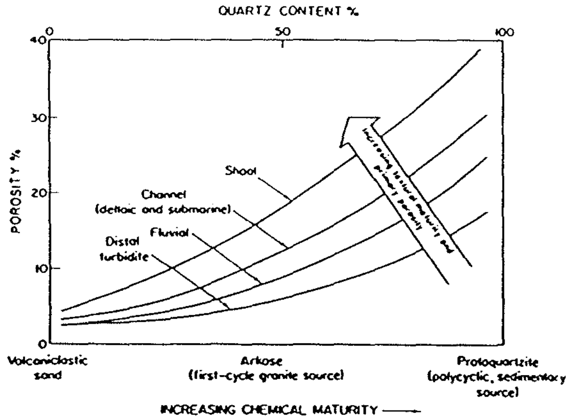

Fig. 12-6 Interrelationships among porosity, mineral composition, and environment of deposition of Jurassic sandstones in the North Sea area. (From R. C. Selley, 1978, *Jour. Geol. Soc.*, 135, 126. Used by permission of the Geological Society.)

in the sand and undercompaction of the mud (Sec. 5.12). The effect of clay mineralogy on compaction of muds can be traced primarily to the presence of smectites or interlayered smectite-illite clays. Smectitic clays contain more water than illitic or kaolinitic clays and resist compaction of the mud.

Burst (1969) has suggested that the compaction of clays proceeds in three main stages. In the first, pore-water and water interlayers beyond two are removed by the action of overburden pressure. At the time of deposition muds may have water contents on the order of 70 to 90%. After a few thousand feet of burial the mud retains only about 30% water by volume, of which 20 to 25% is interlayer water and 5 to 10% is residual pore water. In the second stage, pressure is relatively ineffective as a dehydrating agent. Dehydration proceeds by heating, which removes another 10 to 15% of the water. The second stage begins at temperatures close to 80°C and may be accompanied by diagenetic changes in clay mineralogy. Since this is also the temperature at which organic matter matures to petroleum (Sec. 9.2), is possible that explusion of water during the third stage of clay recrystallization also the cause of the "primary" migration of petroleum from source to reservoir rocks. The third stage of dehydration is also controlled by temperature but apparently is also very slow, requiring tens to hundreds of years to reach completion.

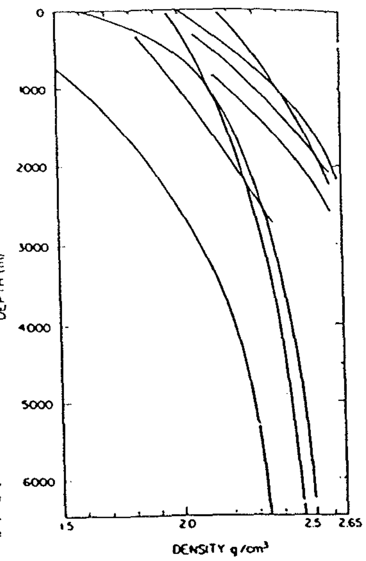

Fig. 12-7 Variation of the bulk density of mudrocks with depth in several sedimentary basins. (From H. H. Rieke, III, and G. V. Chilingar, 1974, *Compaction of Argillaceous Sediments*, Elsevier Pub. Co., p. 34. Used by permission of the Elsevier Scientific Pub. Co.)

Interlayer water is removed completely, leaving only a few percent of pore water in the mudrock.

Authigenesis

Authigenic minerals in sandstones are dominantly calcite and quartz cements but may also be clay minerals (Chap. 9). Authigenesis in both sands and muds is favored by increasing compaction, temperature, and salinity, all of which accompany increased depth of burial. The relationship between burial depth and the formation of secondary growths on detrital quartz grains is illustrated for some Mesozoic sandstones by Füchtbauer (1967) (Fig. 12-8). In some rocks, however, authigenesis may preserve rather then destroy porosity. Lumsden et al. (1971) found that authigenic chlorite coatings on detrital quartz grains in the Spiro and Foster Sands (Pennsylvanian, Oklahoma) preserve the bulk of depositional porosity

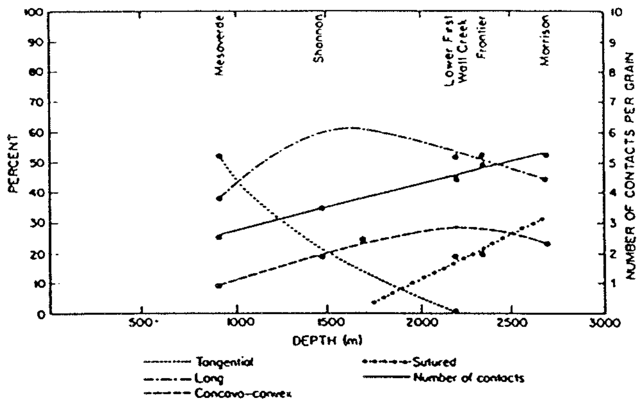

Fig. 12-4 Relationship between depth and type of grain-to-grain contact in thin sections of cores of Mesozoic sandstones in Wyoming. (From J. M. Taylor, 1950, *Amer. Assoc. Pet. Geol. Bull.*, 34, 715. Used by permission of the American Assoc. Petroleum Geologists.)

may have resulted simply from either an increase in percentage of elongate rock fragments with depth or an increase in clay content of the sandstones.

The presence of detrital clay in a sandstone has the same effect as the presence of ductile fragments but increases the rate of compaction. Mud has a very low bearing strength and noticeable compaction of clayey sandstones can occur at depths of only a few meters.

Increased compaction causes a decrease in primary porosity, a feature observed in several field studies. Data relating porosity to burial depth have been collected from large numbers of subsurface cores in different sedimentary basins (Fig. 12-5), and it was found that porosity can decrease either linearly or nonlinearly with depth and at greatly differing rates. Petrographic studies are needed to determine the causes of these differences. The interrelationships among porosity, textural maturity, and mineralogic composition are well illustrated by Selley (1978) in a study of the occurrence of oil in Jurassic sandstones in the North Sea area (Fig. 12-6). Volcaniclastic sands are easily altered chemically during diagenesis to produce fine-grained matrix. Nearly pure quartz sandstones suffer least from diagenetic effects. Arkoses occupy an intermediate position with respect to diagenetic effects. With respect to texture, the situation in the Jurassic rocks is equally clear, with shallow environments being most texturally mature, distal turbidites the least.

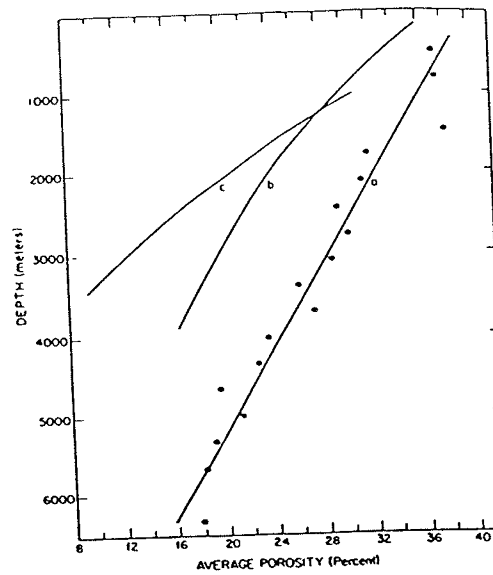

Fig. 12-5 Porosity vs. depth. (a) South Louisiana Tertiary sands; 17,367 samples. (From G. I. Atwater and E. E. Miller, 1965, unpub. ms.; data averaged for each 1000 ft. interval); (b) Great Valley Cretaceous and Tertiary sands; 165 reservoirs. (From D. L. Ziegler, and J. H. Spotts, 1978, *Amer. Assoc. Pet. Geol. Bull.*, 62, 814; (c) Cis-Caucasus, U.S.S.R.; 93 samples. (From B. K. Proshlyakov, 1960, trans. by Assoc. Tech. Serv., Inc., N.J., 1965, p. 3.)

The compaction of muds is considerably more complex than that of sandstones, as Meade (1966) has described. In the early stages, compaction may depend strongly on several factors in addition to depth of burial: grain size, rate of deposition, clay mineralogy, content of organic matter, and geochemical factors (Chapter 11). Variations in these parameters cause wide variations in the amount of compaction suffered by different muds at the same burial depth (Fig. 12-7). Coarser grain size correlates with increased quartz/clay ratio and hence reduced compaction. High rates of deposition can result in the formation of clay "seals" above sand units, which destroy vertical permeability and cause the formation of excess pore pressure

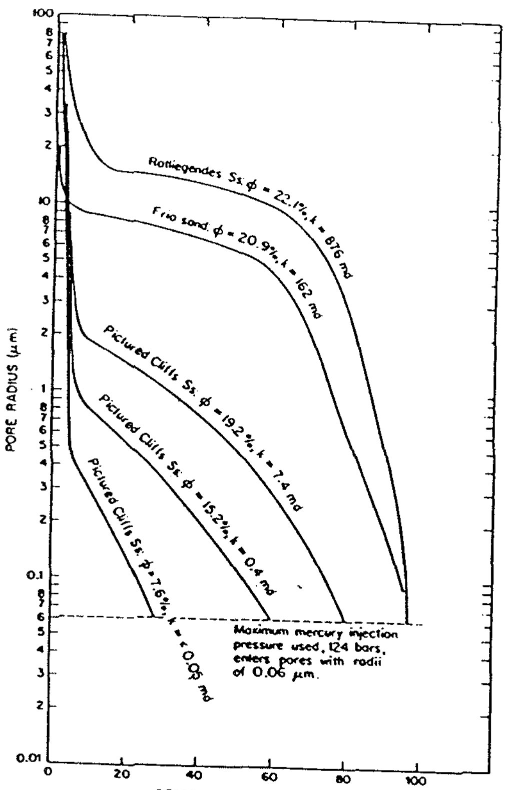

Fig. 12-3 Relationships among total porosity (ϕ), permeability (k), and pore radius of five sandstone cores (courtesy of Amoco Production Company). Total porosity determined by gas expansion. For the three relatively impermeable sandstones, the majority of the pore throat radii are less than 0.5 μm.

to 0.01 μm or less at a depth of 3000 m. These values are an order of magnitude smaller than those typical of sandstones (see Fig. 12-3).

The quantitative significance of the sorting of sand grains on porosity of a sandstone was studied experimentally by Beard and Weyl (1973) for gaussian distributions. Porosity was essentially independent of grain size but decreased sequentially as sorting decreased from 42.4% porosity in extremely well-sorted sands to 27.9% in very poorly sorted sands with no clay matrix. This result seems quite reasonable because smaller grains will lodge between the larger ones. Pryor (1973) found no significant change in the porosity of river, beach, and dune sands with change in standard deviation from 0.3ϕ to 1.6ϕ, but his core samples, unlike those in the Beard and Weyl study, were not homogeneous. Pryor's cores consisted of many thin, individually well-sorted laminae so that although porosity would be excellent, the sediment sorting determined in the laboratory might be good or poor for the core as a unit.

The porosity of a sandstone depends on postdepositional factors as well as those present at the time and site of deposition. As noted, the most important factors during deposition are clay content and the sorting of the sand fraction of the sediment. Of lesser importance are initial grain packing, sand mineralogy, mean grain size (assuming constant sorting), and grain angularity. Important postdepositional or diagenetic factors are degree of compaction and the formation of authigenic minerals.

Compaction

Upon burial, sands compact much less than mudrocks. The lesser compaction of sands results from two factors. First, the average sandstone is composed largely of quartz grains, and these grains are undeformable under most sedimentary conditions. Secondly, the finer particles that predominate in mudrocks are deposited with initially higher water contents and this water is quickly expelled. Many investigators have compacted quartz sands in the laboratory with the result that the thickness of the aggregate has decreased only 10 to 15% due to rearrangement of grains and chipping of grain corners.

The amount of compaction increases significantly with the proportion of ductile rock fragments in the detrital fraction of the sand. Such particles as shale, slate, phyllite, and schist deform easily at shallow depth, decreasing porosity (see below) and thinning the stratigraphic section. This decrease in porosity is noticeable in well logs and was first studied in thin sections of subsurface cores by Taylor (1950). She found that the proportions of the four different types of intergranular contacts changed with depth of burial (Fig. 12-4). Tangential contacts decreased rapidly in abundance with depth, whereas the other three types showed marked increases. Grains were being pushed close together as burial depth increased. Unfortunately, Taylor did not keep a close check on changes in mineral composition with depth; so we cannot be certain how much of the increased closeness of grains was due to plastic deformation of elongate ductile fragments and how much tance. Tortuosity in a sandstone is usually between 2 and 3; in loose sediment it is approximately one-half as large. The greater the tortuosity, the slower the flow of fluid through the pore system.

The physical principle on which the mercury injection method is based is that liquids forming contact angles on solid surfaces of more than 90° (i.e., nonwetting fluids) cannot penetrate into small pores unless the injection pressure exceeds the capillary pressure. The higher the injection pressure, the smaller the pores that can be penetrated by the liquid. In circular pores with radius r the surface tension σ acts along the perimeter of the circle with the force $-2\pi r\sigma$. The force counteracting the intrusion of the liquid parallel to the axis of the pore is $-2\pi r\sigma \cos \lambda$, where λ is the angle of contact. The force caused by the injection pressure p is $\pi r^2 p$. For equilibrium, we obtain

$$-2\pi r\sigma \cos \lambda = \pi r^2 p$$

or

$$r = -\frac{2\sigma \cos \lambda}{p}$$

The surface tension of mercury is 484.2 dynes/cm at 25°C, and the angle of contact of mercury on silicate mineral surfaces has been determined experimentally to approximate 141.3°. Using these values,

$$r = \frac{7.6}{p}$$

when pressure is measured in bars and pore radii in micrometers (Fig. 12-2). Using this relationship, mercury injection of a core yields the volume percentage of pore throats of any given size in the rock sample (Fig. 12-3).

The porosity of mudrocks varies over essentially the same range as in sandstones, from zero to about 40%, but the definition of porosity in a mudrock is not as clear-cut as in the coarser-grained rocks. Indeed, the definition and measurement of porosity in mudrocks present problems not encountered in sandstones. In a sandstone composed primarily of quartz and similar minerals, the boundary between pore space and grain is reasonably well defined. For example, if the pore space is filled with water, then this free or movable water represents the porosity. The proportion of adsorbed or bound water is usually negligible because the specific surface of such minerals as quartz is only 1 to 2 m^2/g of sediment. (Compare with clay minerals below.) In subsurface studies, logging methods that measure total hydrogen concentration, such as neutron logging, effectively measure the porosity. But mudrocks present a more complex problem. Many of the clay minerals contain water as part of their structure, and this water certainly should be considered part of the solid rather than part of the pore space. In addition, water adsorbed on the surface of the clay flakes normally is not free to move, and water may form a large percentage of the total water between clay flakes in mudrock. This situation occurs because the specific surface of clay minerals is very large, on the order of tens of square meters per gram. Within the space between the grains and their adsorbed water, however, there exists free water

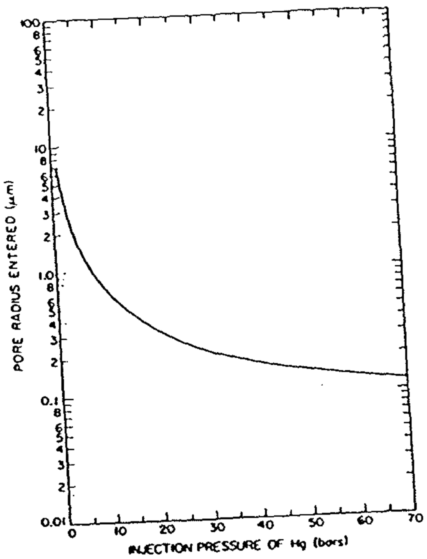

Fig. 12-2 Relationship between injection pressure of mercury into a core and the radii of pore throats that are penetrated.

capable of moving or being easily removed by compaction. Thus when we speak of mudrock porosity, we usually mean the percentage of the total volume of the rock that contains free or easily movable water. It is usually measured by mechanically compacting the rock and measuring the amount of fluid removed or the percentage of volume reduction. These methods are, at best, an approximation of the true pore volume because of the possibility of altering the water content of the clay flakes or the amount of adsorbed water during the analysis.

The critical differences in pore characteristics between sandstones and mudrocks are the sizes and shapes of the pores. Particularly in fissile mudrocks (shales), the clay mineral flakes that form 60% of the mineral grains are oriented in parallel and hence pore spaces are dominantly tabular. Furthermore, because flat flakes can be very closely packed, pore sizes are much smaller. Heling (1970) studied the fabric of Tertiary shales from the Rhinegraben that were buried to depths up to 3400 m. Pore radii decreased from an average of 0.04 μm at a depth of 100 m

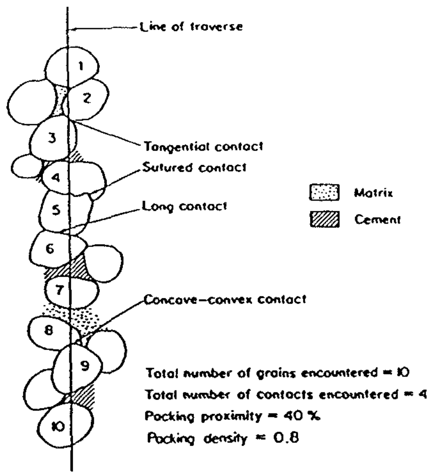

Fig. 12-1 Definition of grain contact types and packing proximity. (After J. M. Taylor, 1950, *Amer. Assoc. Pet. Geol. Bull.*, 34, p. 711, 712, and J. S. Kahn, 1956, *Jour. Geol.*, 64, p. 393).

grain volume; and effective porosity, the ratio of interconnected void volume to total rock volume. In detrital silicate rocks, effective porosity is usually only slightly less than total porosity.

Methods of Measurement

Cores of rocks used for porosity determination are normally cylinders one inch long and one inch in diameter. The porosity can be easily determined by gas expansion, using Boyle's law. Alternatively, the grain density can be assumed (2.65) and the porosity determined by weighing a sample saturated with a fluid of known density. These experimental methods are suitably accurate and are the standards for calibration of all other porosity-determining methods, such as point counts in rock thin sections or subsurface logging techniques. An important point to keep in mind, however, is that the porosity of 13 cm^3 of rock may not be representative of a rock unit millions of times larger in volume, particularly because field observations reveal that porosities can vary greatly over small distances with such factors as clay mineral or rock fragment content.

The use of subsurface logging techniques (sonic, density, neutron) can sometimes produce porosity values within 1% of the value obtained on the same rock in a core sample. The advantages of logging methods over core analysis for porosity determination lie in the much larger volume of rock "sampled," perhaps 100 times larger than the laboratory core, and in the fact that the measurement is made *in situ*, before overburden pressure is removed. In addition, there is the matter of cost. Electric logs are made of all wells, but cores are taken in relatively few.

In most sandstones the bulk of pore space has diameters less than the 30 μm thickness of a standard thin section and so is difficult or impossible to detect during examination of the slide unless special techniques are used. The usual technique is to vacuum-impregnate the rock slice with a colored epoxy before thin sectioning so that even extremely narrow pores that intersect the plane of the thin section become visible in uncrossed nicols. This technique, now standard in industry laboratories, also makes it possible to distinguish between pores produced by diagenetic dissolution of detrital grains and pseudopores produced by grain plucking during grinding of the thin section.

Pore Sizes, Geometry, and Measurement

Pores are irregularly shaped cavities in a rock; therefore any definition of their "size" is an approximation based on the measurement technique used to determine it. In some cases, it is possible to vacuum-impregnate a porous rock with either a molten plastic or metal and then dissolve the rock by using suitable reagents to produce a "negative image" of the rock—that is, its three-dimensional pore network (Swanson, 1979). This technique, although useful for some research purposes, is impractical as a standard method.

The distribution of pore sizes in a rock sample is determined generally by injection of mercury into the rock. The sizes of pores determined in this way are actually the sizes of the pore "throats" or narrow connections between large pores. It is the sizes of the throats that control the flow of fluid through rocks, whether the flow is of mercury during measurement of porosity or is water, petroleum, or natural gas in the subsurface. One deficiency of the mercury injection technique is that if a large pore, such as a vug, is entered by fluid through a narrow throat, the large vug will be included within the volume of pore space represented by the throat size. A second deficiency is that not all pores can be invaded by the mercury because they may be shielded by other smaller pores whose displacement pressure is not exceeded.

The individual pore may be tubular like a capillary tube; or it may be nodular and feather out into the bounding constrictions between nodules; or it may be a thin, intercrystalline tabular opening that is 50 to 100 times as wide as it is thick. The wall of the pore may be clean quartz, feldspar, or calcite; or it may be coated with clay mineral particles, platey accessory minerals, or rock fragments. The crookedness of the pore pattern, called the *tortuosity*, is the ratio between the distance between two points by way of the connected pores and the straight-line dis-

CHAPTER 12

POROSITY AND PERMEABILITY OF DETRITAL ROCKS

12.1 INTRODUCTION

The porosity and permeability of sandstones and mudrocks have been generally neglected by academic geologists. Most of our knowledge in this area comes from the petroleum industry as part of its effort to locate reserves of oil and gas. It is strange that few geologists outside of industry have investigated the porosities and permeabilities of detrital rocks, for these variables control most diagenetic processes in rocks. Without adequate permeability to water there can be little cementation of sandstones, diagenetic alteration of heavy minerals, conversion of smectite to illite, or the myriad of other processes that affect rock after burial. Pore space and permeability are basic aspects of rock fabric and should be studied as a normal part of a petrologic investigation.

12.2 FABRIC

The term *fabric* is reserved for "the manner of mutual arrangement in space of the components of a rock body and of the boundaries between these components" (*International Tectonics Dictionary*). It thus includes both the packing

and orientation of grains. Grain packing strongly affects both porosity and permeability and grain orientation affects the permeability (Sec. 12.4).

The least-studied aspect of fabric is *packing*, "the spacing or density pattern of mineral grains in a rock" (AGI Glossary). The meaning of packing and its distinction from other aspects of fabric, such as orientation, is most clearly seen for the case of a sediment composed of perfect spheres uniform in size. Even in this highly idealized case it has been shown that there are six different systematic ways of arranging the spheres so that each sphere is in contact with four or more adjacent spheres and there are no vacant positions. The arrangements vary from the "loosest" cubic packing with a porosity of 47.6% to the "tightest" rhombohedral packing with a porosity of 26.0%. The six regular packings do not exhaust the number of ways that spheres may, in fact, be packed because in nature an infinite number of combinations of the six and of "random" packings may also be developed.

Kahn (1956) devised two numerical measures for use in thin section studies.

1. The *packing density* is the ratio of the sum of the lengths of grain intercepts to the total length of the traverse across the thin section. It is a measure of the porosity of a cement-and matrix-free sand or of the "matrix-cement-free porosity" of a sandstone that has some matrix and cement.
2. The *packing proximity* is the ratio of the number of grain-to-grain contacts (encountered in a traverse across the thin section) to the total number of contacts of all kinds encountered in the same traverse (Fig. 12-1). If the grains have only small areas of contact with each other, most of the contacts observed in a thin section will be contacts between a grain and matrix or cement; so the packing proximity will be small. In a rock in which there has been compaction without the introduction of much cement, most of the grain contacts observed will be grain-to-grain contacts and the packing proximity will be large.

The type of contact between grains can also be studied in thin section. In the ideal case of packed spheres, the only observed contacts between grains would be tangential ones. But in the case of nonspherical grains or where compaction has taken place, three other types of contacts can be observed (Taylor, 1950). The four possible types of contacts are (a) tangential, (b) long—that is, a contact that appears as a straight line in the plane of section, (c) concavoconvex, and (d) sutured. The frequency of concavoconvex and sutured contacts relative to that of other types of contacts has been used as a measure of the intensity of compaction of sands.

12.3. POROSITY

Several terms are widely used to indicate the amount of pore space in a rock. The most common are porosity, the ratio of void volume to total rock volume (multiplied by 100 to form a percentage); void ratio, the ratio of pore volume to

APPENDIX G

Slope Stability

PURPOSE:

Stability Analysis of the Side Slopes of the Cover

The purpose of this calculation brief is to evaluate stability of the side slopes of the cover for the uranium tailings impoundments. The sides of the covers are sloped at 5H:1V. From the old drawings as published by UMETCO (section B-B), the side slope for Cell 4 is the tallest. Also, along the southern section of Cell 4, the ground elevation drops rapidly. Hence the side slopes of the cover located along the southern side of Cell 4 are assumed to be critical and considered for stability analysis.

METHODOLOGY:

Static and pseudostatic slope stability analyses have been performed for the slope geometry as shown in Figure 1. The limit equilibrium slope stability code GSLOPE, developed by MITRE Software Corporation has been used for these analyes. The Bishop's method of slices has been applied.

Geometry and Material Properties

Along the southern end of Cell 4, the topography drops at a rate of approximately 5.5% (Figure 2). The material properties as provided by Dames and Moore, 1978, have been used for these analyses. The material properties have been listed in Table 1, below.

Material No.	Type of Material	Unit weight, γ (pcf)	Cohesion, c (psf)	Angle of friction, ϕ (degrees)
1	Earthfill	123	0	30
2	Tailings	62.4	0	0
3	Dike	123	0	30
4	Foundation	120	0	28
5	Bedrock	130	10,000	45

Table 1: Material Properties

The surface of the bedrock has been determined from the bore-logs as supplied by Chen and Associates, 1978. But as this bedrock surface almost coincides with that of the foundation, assuming the bedrock layer to be about 10 ft. below the lowest point of the foundation surface, will give conservative results. Thus, for the stability analysis, the surface of competent bedrock has been assumed to be at an elevation of +5540 ft. above mean sea level (MSL).

Factor of Safety and Horizontal Acceleration required for analysis:
A factor of safety of 1.5 and 1.0 are respectively acceptable for static and pseudostatic analyses. Pseudostatic slope stability analysis has been performed for a maximum seismic coefficient of 0.1g.

RESULTS:

Results of the stability analyses have been presented in this calculation document.
Results for Static case: For static analysis, the maximum Factor of Safety calculated is 2.91 (>1.5).
Results for Pseudostatic case: For pseudostatic analysis, the maximum Factor of Safety calculated is 1.903 (>1.0) for a ground acceleration of 0.1g.

Hence the side slopes are stable.

PURPOSE:

Pseudostatic Slope Stability Analysis of the Side Slopes of the Cover for horizontal acceleration of 0.12g

The purpose of this calculation brief is to evaluate pseudostatic stability of the side slopes of the cover for the uranium tailings impoundments for a horizontal ground acceleration of 0.12g. The sides of the covers are sloped at 5H:1V. From the old drawings as published by UMETCO (section B-B), the side slope for Cell 4 is the tallest. Also, along the southern section of Cell 4, the ground elevation drops rapidly. Hence the side slopes of the cover located along the southern side of Cell 4 are assumed to be critical and considered for stability analysis.

METHODOLOGY:

Pseudostatic slope stability analyses have been performed for the slope geometry as shown in Figure 1. The limit equilibrium slope stability code GSLOPE, developed by MITRE Software Corporation has been used for these analyes. The Bishop's method of slices has been applied.

Geometry and Material Properties

Along the southern end of Cell 4, the topography drops at a rate of approximately 5.5% (Figure 2). The material properties as provided by Dames and Moore, 1978, have been used for these analyses. The material properties have been listed in Table 1, below.

Material No.	Type of Material	Unit weight, γ (pcf)	Cohesion, c (psf)	Angle of friction, ϕ (degrees)
1	Earthfill	123	0	30
2	Tailings	62.4	0	0
3	Dike	123	0	30
4	Foundation	120	0	28
5	Bedrock	130	10,000	45

Table 1: Material Properties

The surface of the bedrock has been determined from the bore-logs as supplied by Chen and Associates, 1978. But as this bedrock surface almost coincides with that of the foundation, assuming the bedrock layer to be about 10 ft. below the lowest point of the foundation surface, will give conservative results. Thus, for the stability analysis, the surface of competent bedrock has been assumed to be at an elevation of +5540 ft. above mean sea level (MSL).

Factor of Safety and Horizontal Acceleration required for analysis:

A factor of safety of 1.0 is acceptable for pseudostatic. Pseudostatic slope stability analysis has been performed for a maximum seismic coefficient of 0.12g as recommended by the Lawrence Livermore National Laboratory.

RESULTS:

Results for Pseudostatic case: For pseudostatic analysis, the maximum Factor of Safety calculated is 1.778 (>1.0) for a ground acceleration of 0.12g.

Hence the side slopes are stable.

Sand (SM), silty, fine to medium grained, approximately 40-50% silt, slightly moist to moist, reddish brown.

Sand, silty to sandy silt (SM-ML), fine to medium grained, approximately 50-60% silt, slightly moist to moist, reddish brown.

Silt (ML), sandy, approximately 60-70% silt, fine to medium sand size, slightly calcareous with depth, slightly moist to moist, reddish brown to light brown.

Clay, silty to sandy silt (CL-ML), approximately 60-75% low to non-plastic fines, fine to medium sand size, slightly to moderately calcareous with depth, slightly moist, light brown.

Clay (CL), highly calcareous, sandy to silty, approximately 50-75% low plasticity fines, scattered very hard lenses/layer, dry to slightly moist, light tan to white.

Weathered claystone (CL-CH), approximately 90% medium to high plasticity fines, moist, gray-brown.

Claystone, bedrock, slightly moist, greenish gray.

Claystone-sandstone bedrock, lightly cemented, roughly stratified, fine to medium grained, greenish gray.

Sandstone bedrock, well cemented with depth, fine to medium grained, tan to gray.

Disturbed auger sample.

NOTES:

(1) Test holes were drilling on May 17 and 18, 1978 with a 12-inch, single-flight, power auger.
(2) Elevations are approximate and taken from contours shown on Fig. 1.
(3) No free water was found in test holes at the time of drilling.
(4) WC = Water Content (%);
-200 = Percent Passing No. 200 Sieve;
LL = Liquid Limit (%);
PI = Plasticity Index (%)
NP = Non-Plastic.

3.8 Stability

3.8.1 Slope Stability

The external dikes formed by cover placement on Cell 2 will be extended to a reclaimed slope of 5(H) to 1(V) but may exist on an interim basis as 3(H) to 1(V) slopes until final reclamation. A stability analysis was performed using the 3(H) to 1(V) slopes. The maximum section of the dike will have a 15-foot wide berm at its base. The soil strength parameters used in the analysis are those developed by Dames & Moore (1978a) and are as follows:

Soil Parameters
for
Slope Stability Analysis

Section	Density (Pcf)	(Degrees)	C (psf)
Embankment	123	30	0
Tailings	62.4	0	0
Foundation Soils	120	28	0
Bedrock	130	45	10,000

Material Quantities

TITAN Environmental

By TAM Date 7/5/96 Subject EFN - White Mesa Page 1 of 8
Chkd By KEJ Date 8/14/96 Tailings Cover Material Volume Calc. Proj No 6111-001

Purpose: To determine the volume of riprap, clay, and random fill materials required to construct the uranium mill tailings cover at White Mesa Mill in Blanding, Utah.

Material volumes were calculated for two construction options:

- An integrated soil cover over Disposal Cells 2, 3, and 4A, and
- A cover over Cells 2 and 3, where Cell 4A tailings are excavated and placed in Cell 3.

Method: Standard geometric equations, as shown below, were used to determine the required material volumes.

Volume of a rectangle	= base * height * length
Volume of a trapezoid	= 1/2 * height *($base_1$ + $base_2$)

Surface area calculations for the tops of Cells 2, 3, and 4A are shown in Figure 1, and material volumes are calculated in Table 1.

The method for calculating material volumes on the side slopes is shown in Figure 2. The 5H:1V slopes have been divided into several zones which are indicated on Figure 1. The slopes have been categorized based on the average height they attain over a certain length. The height of the cover above the ground surface, along each side, was estimated using the cross sections in Figures 3 - 5. Calculations are presented in Table 2.

Assumptions:

- Random fill will be used to fill the existing freeboard space between the tailings and clay layer of the cover and bring the tailings pile elevations up to the berm elevations. This will create a smooth surface with a slope matching that of the cover. The random fill thickness between the clay and tailings surface will be a minimum of three feet. This random fill volume was not calculated due to the lack of information of the current topography in the tailings piles.

- The 0.2 percent slope on the tailings piles will be created using random fill materials beneath the clay layer of the cover. Cover materials will consist of one foot of clay under two feet of random fill . The top, riprap layer will consist of a minimum three inches on the top of the cover, and one foot on the side slopes.

Results:

Option 1: (Cover on Cells 2, 3, and 4A):

Total volume (Clay):	**=9,857,221 ft3**	**=365,082 yd3**
Total volume (Random fill):	**=19,918,351 ft3**	**=737,717 yd3**
Total volume (Riprap - top cover):	**=2,234,563 ft3**	**=82,762 yd3**
Total volume (Riprap - side slopes):	**=1,122,881 ft3**	**=41,588 yd3**

Option 2: (Cover on Cells 2 and 3):

Total volume (Clay):	**=7,816,884 ft3**	**=289,514 yd3**
Total volume (Random fill):	**=15,804,024 ft3**	**=585,334 yd3**
Total volume (Riprap - top cover):	**=1,754,563 ft3**	**=64,984 yd3**
Total volume (Riprap - side slopes):	**=968,890 ft3**	**=35,885 yd3**

TABLE 1
Volume of materials for top of cover:

Cell #	surface area ft^2				Th (riprap) inches	Th (fill) feet	Th (clay) feet					V (riprap)[1] ft.^3	V(fill)[1] ft.^3	V(clay)[1] ft.^3

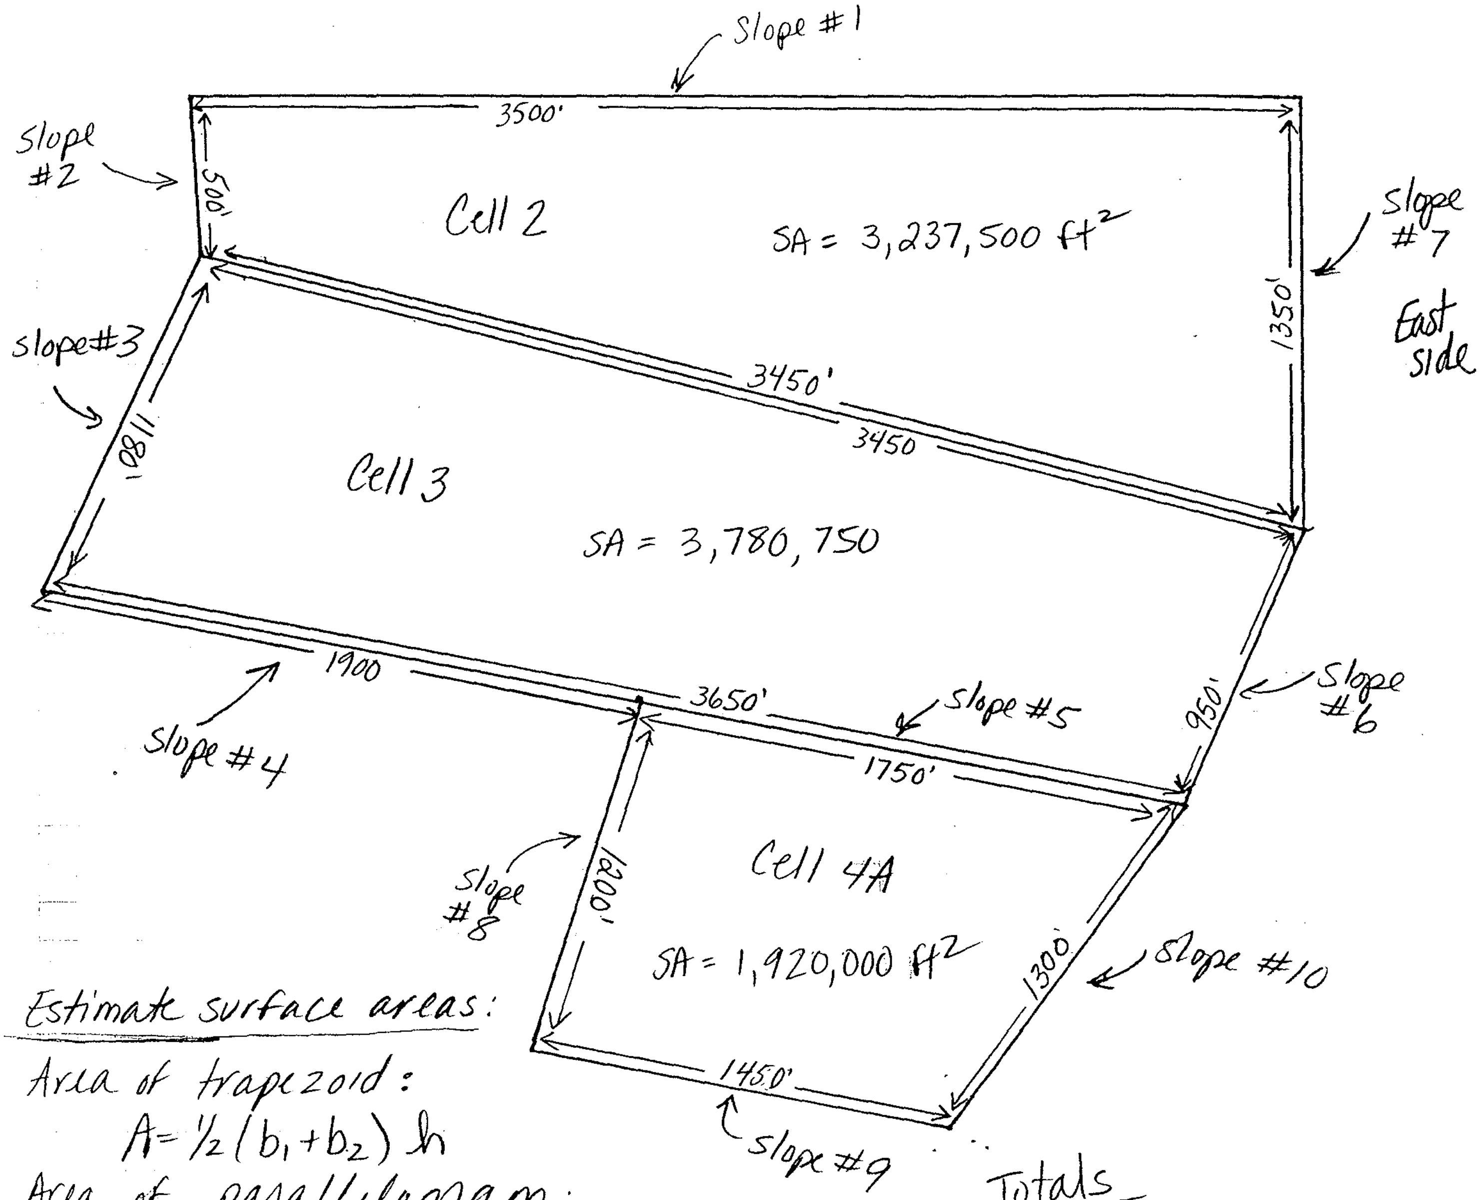
	riprap (side slopes)	1122881 ft^3	41588 yd^3
	random fill	19918351 ft^3	737717 yd^3
	clay	9857221 ft^3	365082 yd^3
Option 2:			
	riprap (top of cover)	1754563 ft^3	64984 yd^3
	riprap (side slopes)	968890 ft^3	35885 yd^3
	random fill	15804024 ft^3	585334 yd^3
	clay	7816884 ft^3	289514 yd^3

Notes:
Riprap on top and sides of cover are of different dimensions, and are therefore caluculated separately.
Total h = the average height along the slope length.
Th = Thickness of the layer of material.
V = Total volume of the material
L' = Length of the layer down the side slope. Calculated as (h(material)) / (cos 78.7). The slope is 5H:1V.
Length = Horizontal length of the side slope.

(1) Volume calculated as (surface area) x (layer thickness).
(2) Volume calculated as (L' x Th x Length).

Surface Areas of Cells

AERIAL VIEW



Estimate surface areas:

Area of trapezoid:

$A = \frac{1}{2}(b_1 + b_2)h$

Area of parallelogram:

$A = bh$

Cell #2

$A = \frac{1}{2}(1350' + 500') \times 3500' = 3,237,500 \text{ ft}^2$

Cell #3

$A = (3550 \times 1065) = 3,780,750 \text{ ft}^2$

Cell #4A

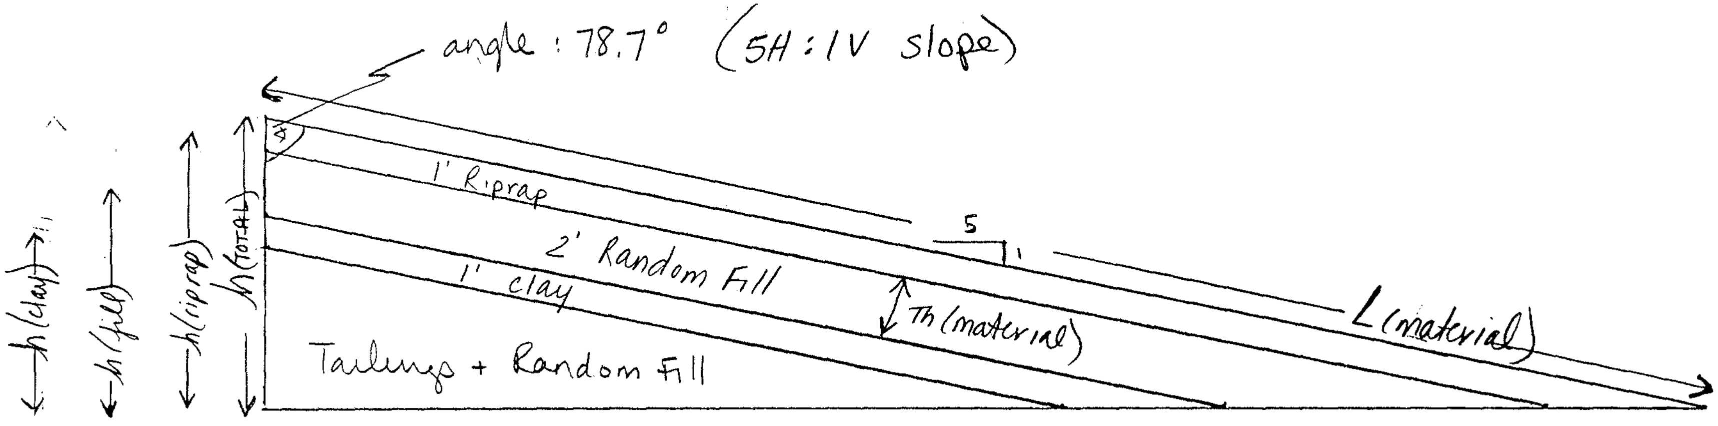
$A = \frac{1}{2}(1450 + 1750) \times 1200 = 1,920,000 \text{ ft}^2$

Totals

1) Option #1
   Cells 2, 3, 4A:
   8,938,250
2) Option #2
   Cells 2, 3:
   7,018,250 ft²

Figure 1

Volumes of Materials along side slopes



L = length of material layer down side slope

$$\cos \measuredangle = \frac{h\,(\text{material})}{L\,(\text{material})}$$

$$L\,(\text{material}) = \frac{h\,(\text{material})}{\cos 78.7}$$

$$V\,(\text{material}) = L\,(\text{material}) \times Th\,(\text{material}) \times \text{Length (from aerial view)}$$

Example: For $h_{\text{TOTAL}} = 16$ ft. (slope #1)

$h_{\text{riprap}} = 16$ ft. − 0.5 ft. = 15.5 ft.

$$L_{\text{riprap}} = \frac{15.5 \text{ ft}}{\cos 78.7} = 79.0 \text{ ft.}$$

$$V_{\text{riprap}} = (79.0')(1.0')(3500') = \underline{276{,}500 \text{ ft}^3}$$

TABLE OF CONTENTS

Page No.

TABLE OF CONTENTS (continued) Page No.

TABLE OF CONTENTS (continued) Page No.

1.0 GENERAL

The specifications presented in this section cover the reclamation of the Mill facilities.

2.0 CELL 1 RECLAMATION

2.1 Scope

The reclamation of Cell 1 (previously referred to as Cell 1-I) consists of evaporating the cell to dryness, removing raffinate crystals, synthetic liner and any contaminated soils, and constructing a clay lined area adjacent to and parallel with the existing Cell 1 dike for permanent disposal of contaminated material and debris from the Mill site decommissioning, referred to as the Cell 1 Tailings Area. A sedimentation basin will then be constructed and a drainage channel provided.

2.2 Removal of Contaminated Materials

2.2.1 Raffinate Crystals

Raffinate crystals will be removed from Cell 1 and transported to the tailings cells. It is anticipated that the crystals will have a consistency similar to a granular material when brought to the cells, with large crystal masses being broken down for transport. Placement of the crystals will be performed as a granular fill, with care being taken to avoid nesting of large sized material. Voids around large material will be filled with finer material or the crystal mass broken down by the placing equipment. Actual placement procedures will be evaluated by the QC officer during construction as crystal materials are brought and placed in the cells.

2.2.2 Synthetic Liner

The PVC liner will be cut up, folded (when necessary), removed from Cell 1, and transported to the tailings cells. The liner material will be spread as flat as practical over the designated area. After placement, the liner will be covered as soon as possible with at least one foot of soil, crystals or other materials for protection against wind, as approved by the QC officer.

2.2.3 Contaminated Soils

The extent of contamination of the Mill site will be determined by a scintillometer survey. If necessary, a correlation between scintillometer readings and U-nat/Radium-226 concentrations will be developed. Scintillometer readings can then be used to define cleanup areas and to monitor the cleanup. Soil sampling will be conducted to confirm that the cleanup results in a concentration of Radium-226 averaged over any area of 100 square meters that does not exceed the background level by more than:

- 5 pCi/g averaged over the first 15 cm of soils below the surface, and
- 15 pCi/g averaged over a 15 cm thick layer of soils more than 15 cm below the surface

Where surveys indicate the above criteria have not been achieved, the soil will be removed to meet the criteria. Soil removed from Cell 1 will be excavated and transported to the tailings cells. Placement and compaction will be in accordance with Section 4.0 of these Plans and Specifications.

2.3 Cell 1 Tailings Area

2.3.1 General

A clay lined area will be constructed adjacent to and parallel with the existing Cell 1 dike for permanent disposal of contaminated material and debris from the Mill site decommissioning (the Cell 1 Tailings Area). The area will be lined with 12 inches of clay prior to placement of contaminated materials and installation of the final reclamation cap.

2.3.2 Materials

Clays will have at least 40 percent passing the No. 200 sieve. The minimum liquid limit of these soils will be 25 and the plasticity index will be 15 or greater. These soils will classify as CL, SC or CH materials under the Unified Soil Classification System.

2.3.3 Borrow Sources

Clay will be obtaned from suitable materials stockpiled on site during cell construction or will be imported from borrow areas located in Section 16, T38S, R22E, SLM.

2.4 Liner Construction

2.4.1 General

Placement of clay liner materials will be based on a schedule determined by the availability of contaminated materials removed from the Mill decommissioning area in order to maintain optimum moisture content of the clay liner prior to placing of contaminated materials

2.4.2 Placement and Compaction

2.4.2.1 Methods

Placement of fill will be monitored by a qualified individual with the authority to stop work and reject material being placed. The full 12 inches of the clay liner fill will be compacted to 95% maximum dry density per ASTM D 698.

In all layers of the clay liner will be such that the liner will, as far as practicable, be free of lenses, pockets, streaks or layers of material differing substantially in texture, gradation or moisture content from the surrounding material. Oversized material will be controlled through selective excavation of stockpiled material, observation of placement by a qualified individual with authority to stop work and reject material being placed and by culling oversized material from the fill.

If the moisture content of any layer of clay liner is outside of the Allowable Placement Moisture Content specified in Table A-5.3.2.1-1, it will be moistened and/or reworked with a harrow, scarifier, or other suitable equipment to a sufficient depth to provide relatively uniform moisture content and a satisfactory bonding surface before the next succeeding layer of clay material is placed. If the compacted surface of any layer of clay liner material is too wet, due to precipitation, for proper compaction of the earthfill material to be placed thereon, it will be reworked with harrow, scarifier or other suitable equipment to reduce the moisture content to the required level shown in Table A-5.3.2.1-1. It will then be recompacted to the earthfill requirements.

No clay material will be placed when either the materials, or the underlying material, is frozen or when ambient temperatures do not permit the placement or compaction of the materials to the specified density, without developing frost lenses in the fill.

2.4.2.2 Moisture and Density Control

As far as practicable, the materials will be brought to the proper moisture content before placement, or moisture will be added to the material by sprinkling on the fill. Each layer of the fill will be conditioned so that the moisture content is uniform throughout the layer prior to and during compaction. The moisture content of the compacted liner material will be within the limits of standard optimum moisture content as shown in Table A-5.3.2.1-1. Material that is too dry or too wet to permit bonding of layers during compaction will be rejected and will be reworked until the moisture content is within the specified limits. Reworking may include removal, re-harrowing, reconditioning, rerolling, or combinations of these procedures.

Density control of compacted clay will be such that the compacted material represented by samples having a dry density less than the values shown in Table A-5.3.2.1-1 will be rejected. Such rejected material will be reworked as necessary and rerolled until a dry density equal to or greater than the percent of its standard Proctor maximum density shown in Table A-5.3.2.1-1.

To determine that the moisture content and dry density requirements of the compacted liner material are being met, field and laboratory tests will be made at specified intervals taken from the compacted fills as specified in Section 7.4, "Frequency of Quality Control Tests."

2.5 Sedimentation Basin

Cell 1 will then be breached and constructed as a sedimentation basin. All runoff from the Mill area and immediately north of the cell will be routed into the sedimentation basin and will discharge onto the natural ground via the channel located at the southwest corner of the basin. The channel is designed to accommodate the PMF flood.

A sedimentation basin will be constructed in Cell 1 as shown in Figure A-2.2.4-1. Grading will be performed to promote drainage and proper functioning of the basin. The drainage channel out of the sedimentation basin will be constructed to the lines and grades as shown.

3.0 MILL DECOMMISSIONING

The following subsections detail decommissioning plans for the Mill buildings and equipment; the Mill site; and windblown contamination.

3.1 Mill

The uranium and vanadium processing areas of the Mill, including all equipment, structures and support facilities, will be decommissioned and disposed of in tailings or buried on site as appropriate. All equipment, including tankage and piping, agitation equipment, process control instrumentation and switchgear, and contaminated structures will be cut up, removed and buried in tailings prior to final cover placement. Concrete structures and foundations will be demolished and removed or covered with soil as appropriate. These decommissioned areas would include, but not be limited to the following:

- Coarse ore bin and associated equipment, conveyors and structures.
- Grind circuit including semi-autogeneous grind (SAG) Mill, screens, pumps and cyclones.
- The three preleach tanks to the east of the Mill building, including all tankage, agitation equipment, pumps and piping.
- The seven leach tanks inside the main Mill building, including all agitation equipment, pumps and piping.
- The counter-current decantation (CCD) circuit including all thickeners and equipment, pumps and piping.
- Uranium precipitation circuit, including all thickeners, pumps and piping.

- The two yellow cake dryers and all mechanical and electrical support equipment, including uranium packaging equipment.
- The clarifiers to the west of the Mill building including the preleach thickener (PLT) and claricone.
- The boiler and all ancillary equipment and buildings.
- The entire vanadium precipitation, drying and fusion circuit.
- All external tankage not included in the previous list including reagent tanks for the storage of acid, ammonia, kerosene, water, dry chemicals, etc. and the vanadium oxidation circuit.
- The uranium and vanadium solvent extraction (SX) circuit including all SX and reagent tankage, mixers and settlers, pumps and piping.
- The SX building.
- The Mill building.
- The Alternate Feed processing circuit
- Decontamination pads
- The office building.
- The shop and warehouse building.
- The sample plant building.
- The Reagent storage building.

The sequence of demolition would proceed so as to allow the maximum use of support areas of the facility such as the office and shop areas. It is anticipated that all major structures and large equipment will be demolished with the use of hydraulic shears. These will speed the process, provide proper sizing of the materials to be placed in tailings, and reduce exposure to radiation and other safety hazards during the demolition. Any uncontaminated or decontaminated equipment to be considered for salvage will be released in accordance with the terms of License

Condition 9.10. As with the equipment for disposal, any contaminated soils from the Mill area will be disposed of in the tailings facilities in accordance with Section 4.0 of the Specifications.

3.2 Mill Site

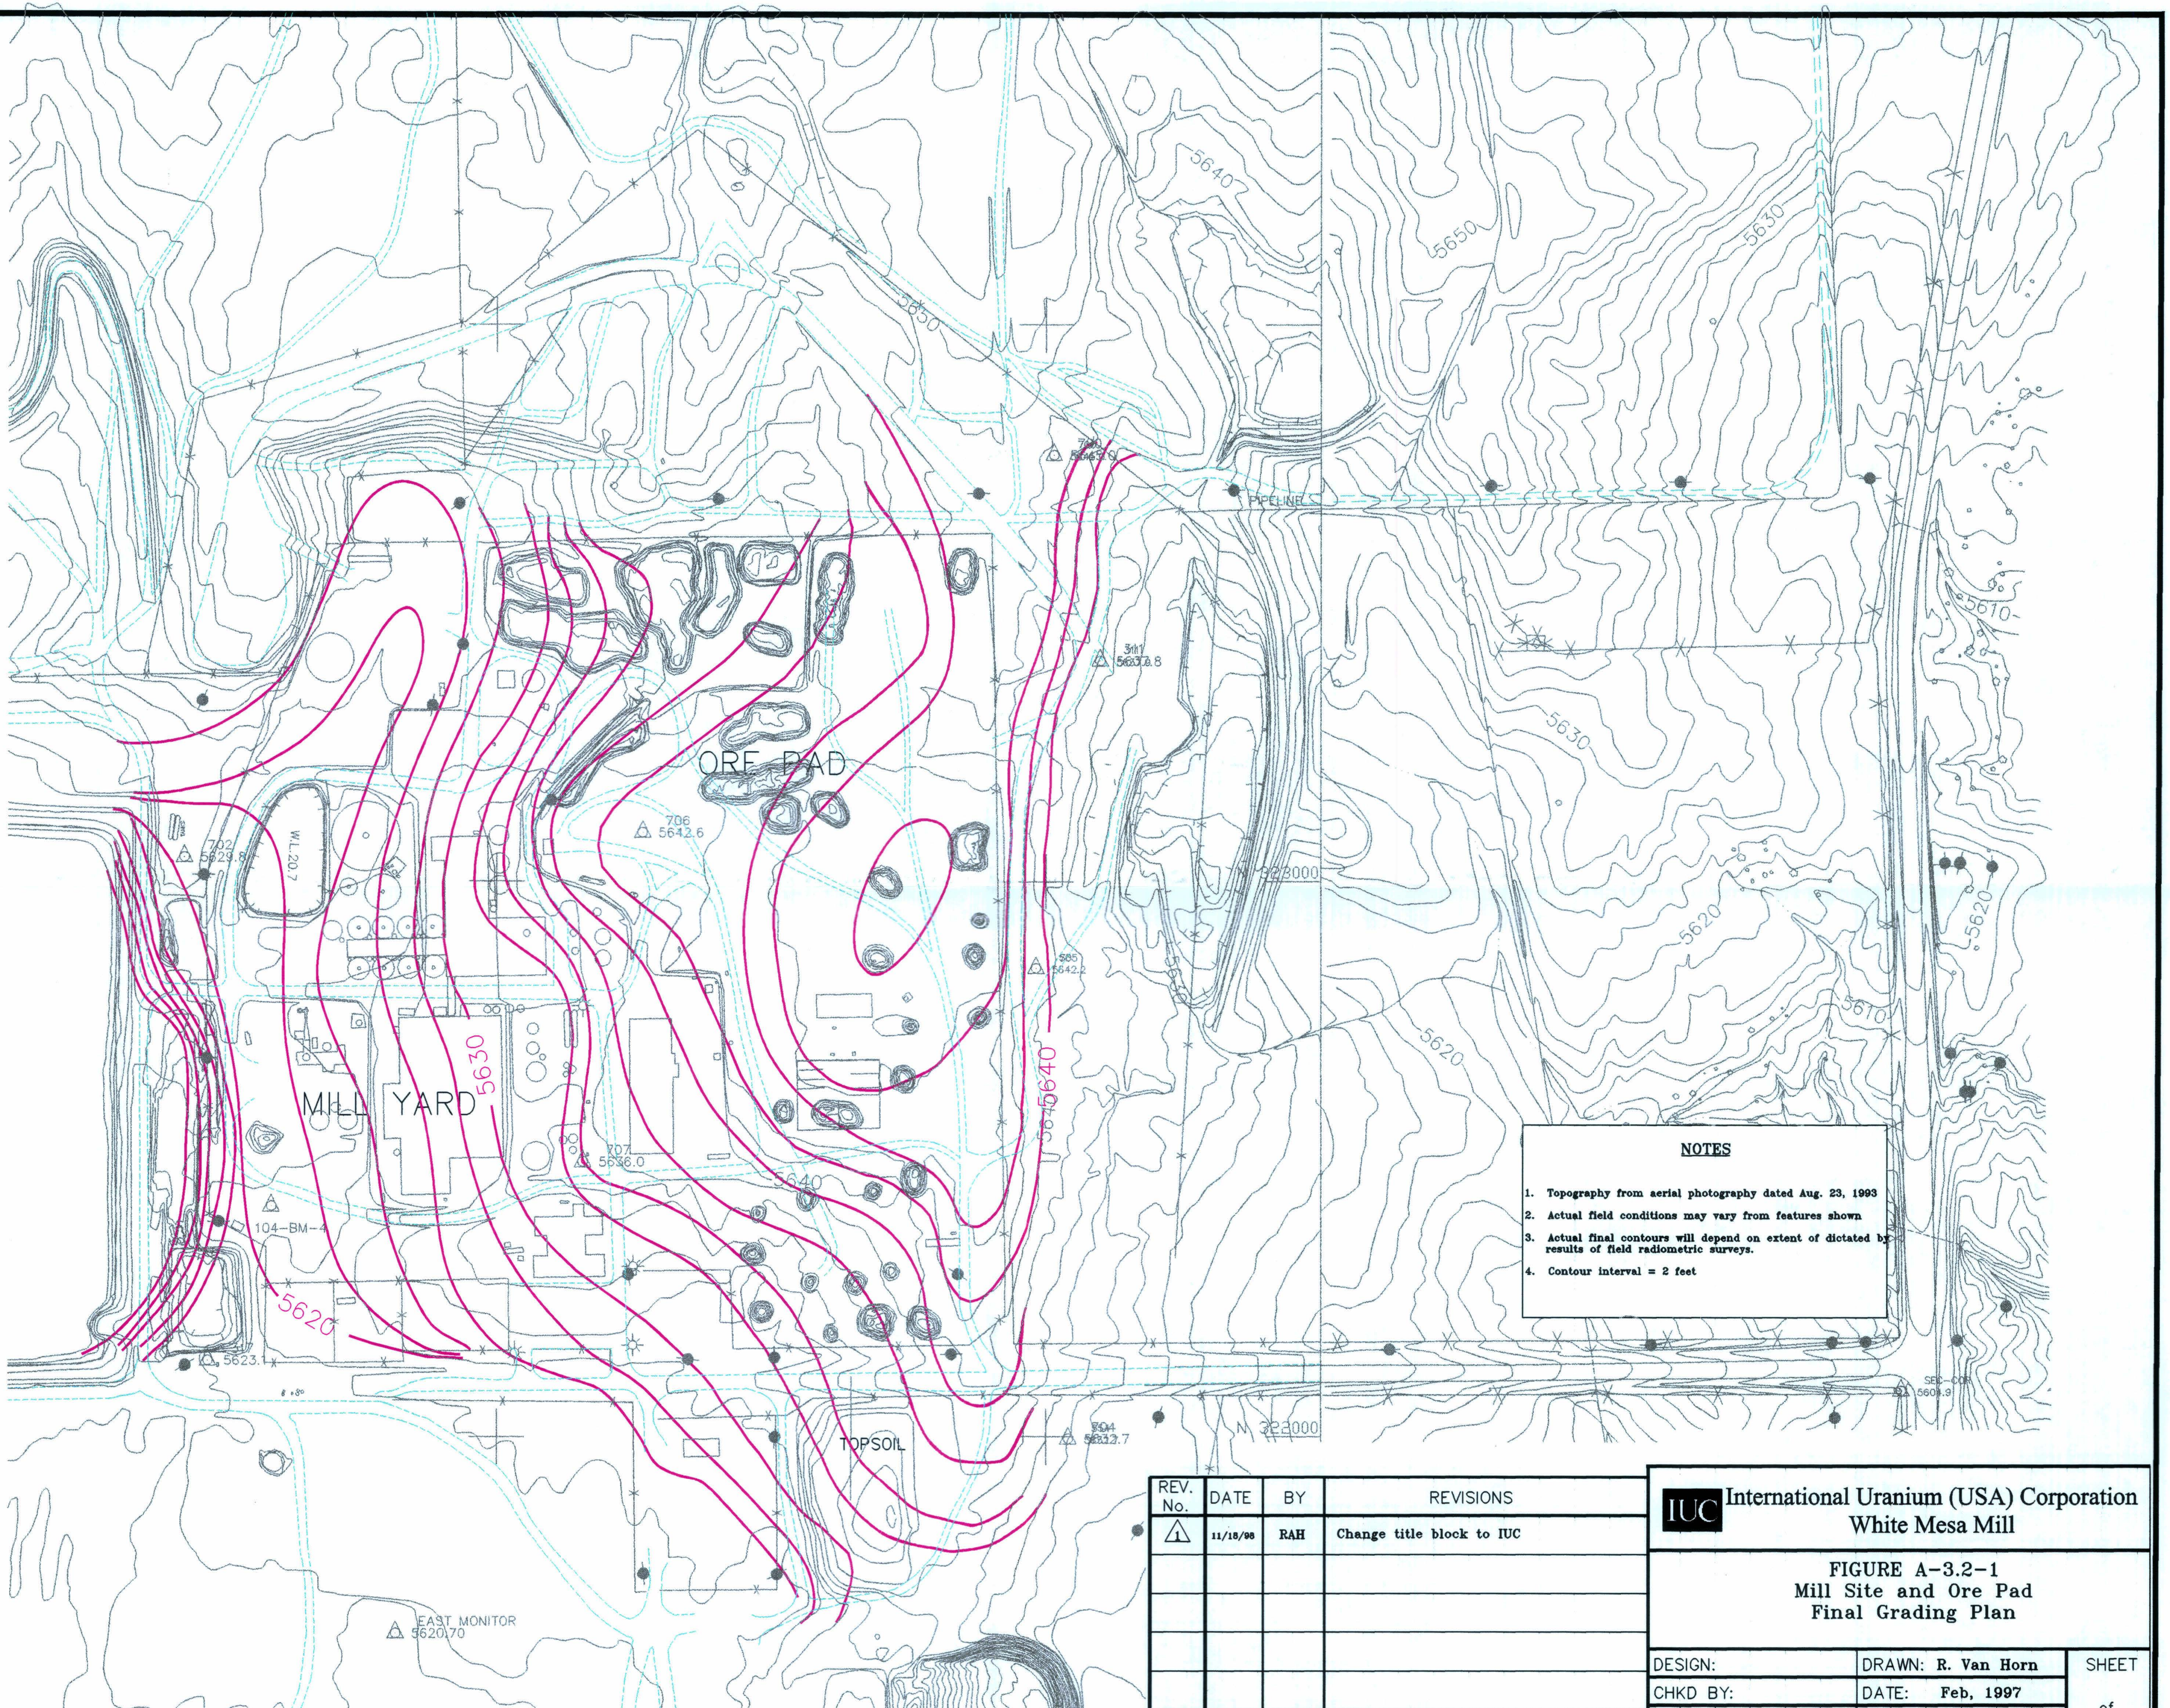
Contaminated areas on the Mill site will be primarily superficial and include the ore storage area and surface contamination of some roads. All ore and alternate feed materials will have been previously removed from the ore stockpile area. All contaminated materials will be excavated and be disposed in one of the tailings cells in accordance with Section 4.0 of these Plans and Specifications. The depth of excavation will vary depending on the extent of contamination and will be based on the criteria in Section 2.2.3 of these Plans and Specifications. All other 11e.(2) byproduct materials will be disposed of in the tailings cells.

All ancillary contaminated materials including pipelines will be removed and will be disposed of by disposal in the tailing cells in accordance with Section 4.0 of these Plans and Specifications.

Disturbed areas will be covered, graded and vegetated as required. The proposed grading plan for the Mill site and ancillary areas is shown on Figure A-3.2-1.

3.3 Windblown Contamination

Windblown contamination is defined as Mill derived contaminants dispersed by the wind to surrounding areas. The potential areas affected by windblown contamination will be surveyed using scintillometers taking into account historical operational data from the Semi-annual Effluent Reports and other guidance such as prevailing wind direction and historical background data. Areas covered by the existing Mill facilities and ore storage pad, the tailings cells and adjacent stockpiles of random fill, clay and topsoil, will be excluded from the survey. Materials from these areas will be removed in conjunction with final reclamation and decommissioning of the Mill and tailings cells.



NOTES

1. Topography from aerial photography dated Aug. 23, 1993
2. Actual field conditions may vary from features shown
3. Actual final contours will depend on extent of dictated by results of field radiometric surveys.
4. Contour interval = 2 feet

3.3.1 Guidance

The necessity for remedial actions will be based upon an evaluation prepared by Denison, and approved by the Executive Secretary, of the potential health hazard presented by any windblown materials identified. The assessment will be based upon analysis of all pertinent radiometric and past land use information and will consider the feasibility, cost-effectiveness, and environmental impact of the proposed remedial activities and final land use. All methods utilized will be consistent with the guidance contained in NUREG-5849: "Manual for Conducting Radiological Surveys in Support of License Termination."

3.3.2 General Methodology

The facility currently monitors soils for the presence of Ra-226, Th-230 and natural uranium, such results being presented in the second semi-annual effluent report for each year. Guideline values for these materials will be determined and will form the basis for the cleanup of the Mill site and surrounding areas. For purposes of determining possible windblown contamination, areas used for processing of uranium ores as well as the tailings and evaporative facilities will be excluded from the initial scoping survey, due to their proximity to the uranium recovery operations. Those areas include:

- The Mill building, including CCD, Pre-Leach Thickener area, uranium drying and packaging, clarifying, and preleach.
- The SX building, including reagent storage immediately to the east of the SX building.
- The alternate feed circuit.
- The ore pad and ore feed areas.
- Tailings Cells No. 2, 3, 4A, and 4B.
- Evaporation Cell No. 1.

The remaining areas of the Mill will be divided up into two areas for purposes of windblown determinations:

- The restricted area, less the above areas; and,
- A halo around the restricted area.

Areas within the restricted area, as shown on Figure 3.2-1 will be initially surveyed on a 30 x 30 meter grid as described below in Section 3.3.3. The halo around the suspected area of contamination will also be initially surveyed on a 50 x 50 meter grid using methodologies described below in Section 3.3.3. Any areas which are found to have elevated activity levels will be further evaluated as described in Sections 3.3.4 and 3.3.5. Initial surveys of the areas surrounding the Mill and tailings area have indicated potential windblown contamination only to the north and east of the Mill ore storage area, and to the southwest of Cell 3, as indicated on Figure 3.2-1.

3.3.3 Scoping Survey

Areas contaminated through process activities or windblown contamination from the tailings areas will be remediated to meet applicable cleanup criteria for Ra-226, Th-230 and natural uranium. Contaminated areas will be remediated such that the residual radionuclides remaining on the site, that are distinguishable from background, will not result in a dose that is greater than that which would result from the radium soil standard (5 pCi/gram above background).

Soil cleanup verification will be accomplished by use of several calibrated beta/gamma instruments. Multiple instruments will be maintained and calibrated to ensure availability during Remediation efforts.

Initial soil samples will be chemically analyzed to determine on-site correlation between the gamma readings and the concentration of radium, thorium and uranium, in the samples. Samples will be taken from areas known to be contaminated with only processed uranium materials (i.e. tailings sand and windblown contamination) and areas in which it is suspected that unprocessed uranium materials (i.e. ore pad and windblown areas downwind of the ore pad) are present. The actual number of samples used will depend on the correlation of the results between gamma readings and the Ra-226 concentration. A minimum of 35 samples of windblown tailings material, and 15 samples of unprocessed ore materials is proposed. Adequate samples will be taken to ensure that graphs can be developed to adequately project the linear regression lines and the calculated upper and lower 95 percent confidence levels for each of the instruments. The 95 percent confidence limit will be used for the guideline value for correlation between gamma readings and radium concentration. Because the unprocessed materials are expected to have proportionally higher values of uranium in relation to the radium and thorium content, the correlation to the beta/gamma readings are expected to be different than readings from areas known to be contaminated with only processed materials. Areas expected to have contamination from both processed and unprocessed materials will be evaluated on the more conservative correlation, or will be cleaned to the radium standard which should ensure that the uranium is removed.

Radium concentration in the samples should range from 25% of the guideline value (5 pCi/gram above background) for the area of interest, through the anticipated upper range of radium contamination. Background radium concentrations have been gathered over a 16 year period at sample station BHV-3 located upwind and 5 miles west of the Mill. The radium background concentration from this sampling is 0.93 pCi/gram. This value will be used as an interim value for the background concentration. Prior to initiating cleanup of windblown contamination, a systematic soil sampling program will be conducted in an area within 3 miles of the site, in geologically similar areas with soil types and soil chemistry similar to the areas to be cleaned, to determine the average background radium concentration, or concentrations, to be ultimately used for the cleanup.

An initial scoping survey for windblown contamination will be conducted based on analysis of all pertinent radiometric and past land use information. The survey will be conducted using calibrated beta/gamma instruments on a 30 meter by 30 meter grid. Additional surveys will be conducted in a halo, or buffer zone, around the projected impact area. The survey in the buffer area will be conducted on a 50 meter by 50 meter grid. Grids where no readings exceed 75% of the guideline value (5 pCi/gram above background) will be classified as unaffected, and will not require remediation.

The survey will be conducted by walking a path within the grid as shown in Figure A-3.3-1. These paths will be designed so that a minimum of 10% of the area within the grid sidelines will be scanned, using an average coverage area for the instrument of one (1) meter wide. The instrument will be swung from side to side at an elevation of six (6) inches above ground level, with the rate of coverage maintained within the recommended duration specified by the specific instrument manufacturer. In no case will the scanning rate be greater than the rate of 0.5 meters per second (m/sec) specified in NUREG/CR-5849 (NRC, 1992).

3.3.4 Characterization and Remediation Control Surveys

After the entire subarea has been classified as affected or unaffected, the affected areas will be further scanned to identify areas of elevated activity requiring cleanup. Such areas will be flagged and sufficient soils removed to, at a minimum, meet activity criteria. Following such remediation, the area will be scanned again to ensure compliance with activity criteria. A calibrated beta/gamma instrument capable of detecting activity levels of less than or equal to 25 percent of the guideline values will be used to scan all the areas of interest.

3.3.5 Final Survey

After removal of contamination, final surveys will be taken over remediated areas. Final surveys will be calculated and documented within specific 10 meter by 10 meter grids with sample point locations as shown in Figure A-3.3.2. Soil samples from 10% of the surveyed grids will be chemically analyzed to confirm the initial correlation factors utilized and confirm the success of cleanup effort for radium, thorium and uranium. Ten (10) percent of the samples chemically analyzed will be split, with a duplicate sent to an off site laboratory. Spikes and blanks, equal in number to 10 percent of the samples that are chemically analyzed, will be processed with the samples.

3.3.6 Employee Health and Safety

Programs currently in place for monitoring of exposures to employees will remain in effect throughout the time period during which tailings cell reclamation, Mill decommissioning and clean up of windblown contamination are conducted. This will include personal monitoring (film badges/TLD's) and the ongoing bioassay program. Access control will be maintained at the Restricted Area boundary to ensure employees and equipment are released from the site in accordance with the current License conditions. In general, no changes to the existing programs are expected and reclamation activities are not expected to increase exposure potential beyond the current levels.

3.3.7 Environment Monitoring

Existing environmental monitoring programs will continue during the time period in which reclamation and decommissioning is conducted. This includes monitoring of surface and groundwater, airborne particulates, radon, soils and vegetation, according to the existing License conditions. In general, no changes to the existing programs are expected and reclamation activities are not expected to increase exposure potential beyond the current levels.

3.3.8 Quality Assurance

At least six (6) months prior to beginning of decommission activities, a detailed Quality Assurance Plan will be submitted for Executive Secretary approval. The Plan will be in accordance with NRC Regulatory Guide 4.15, Quality Assurance for Radiological Monitoring Programs. In general, the Plan will detail Denison's organizational structure and responsibilities, qualifications of personnel, operating procedures and instructions, record keeping and document control, and quality control in the sampling procedure and outside laboratory. The Plan will adopt the existing quality assurance/quality control procedures utilized in compliance with the existing License.

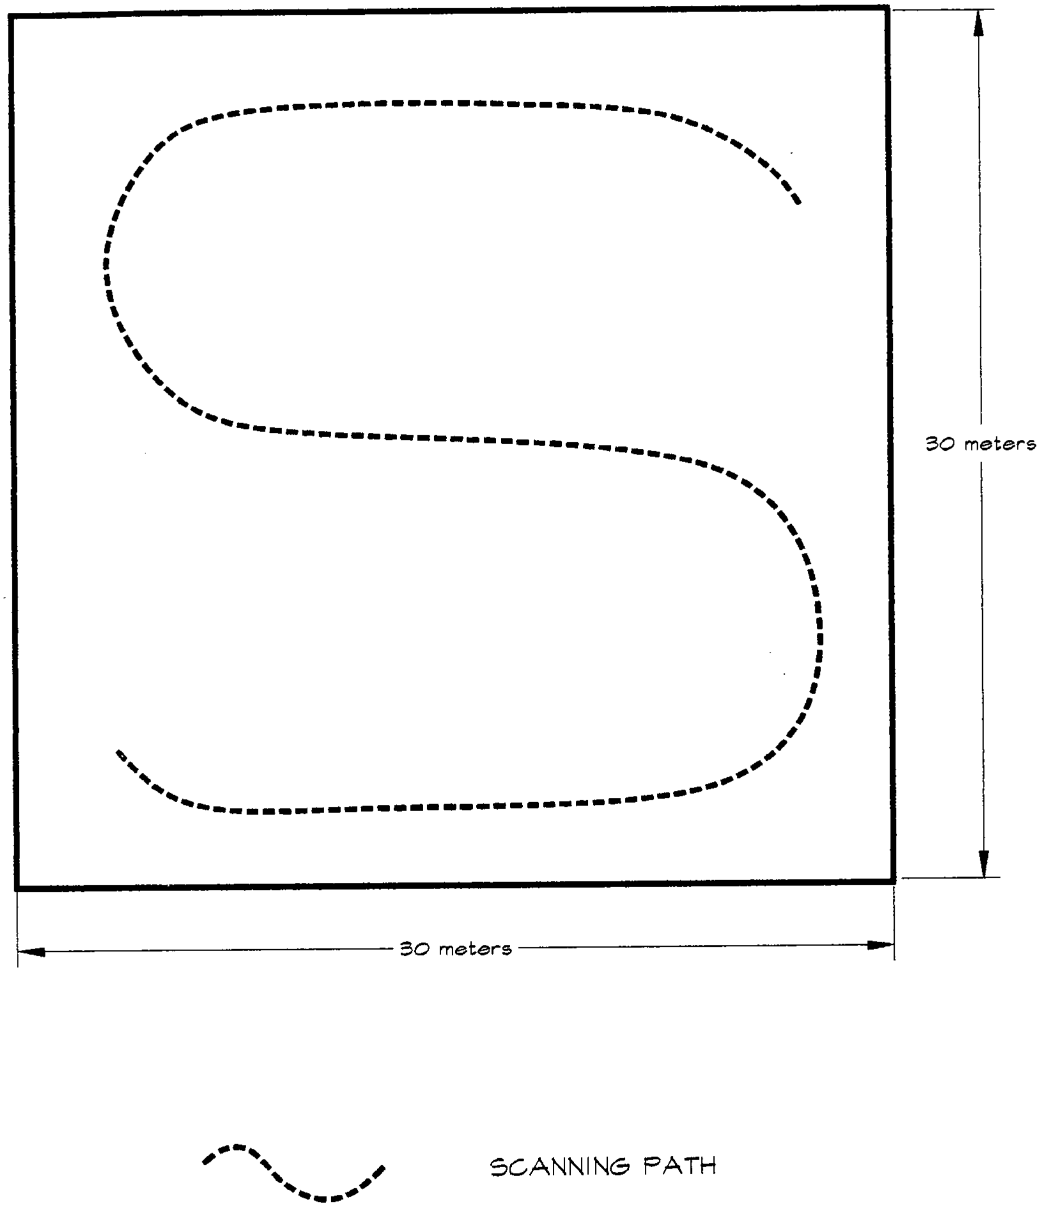

FIGURE A-3.3-1
TYPICAL SCANNING PATH
SCOPING SURVEY

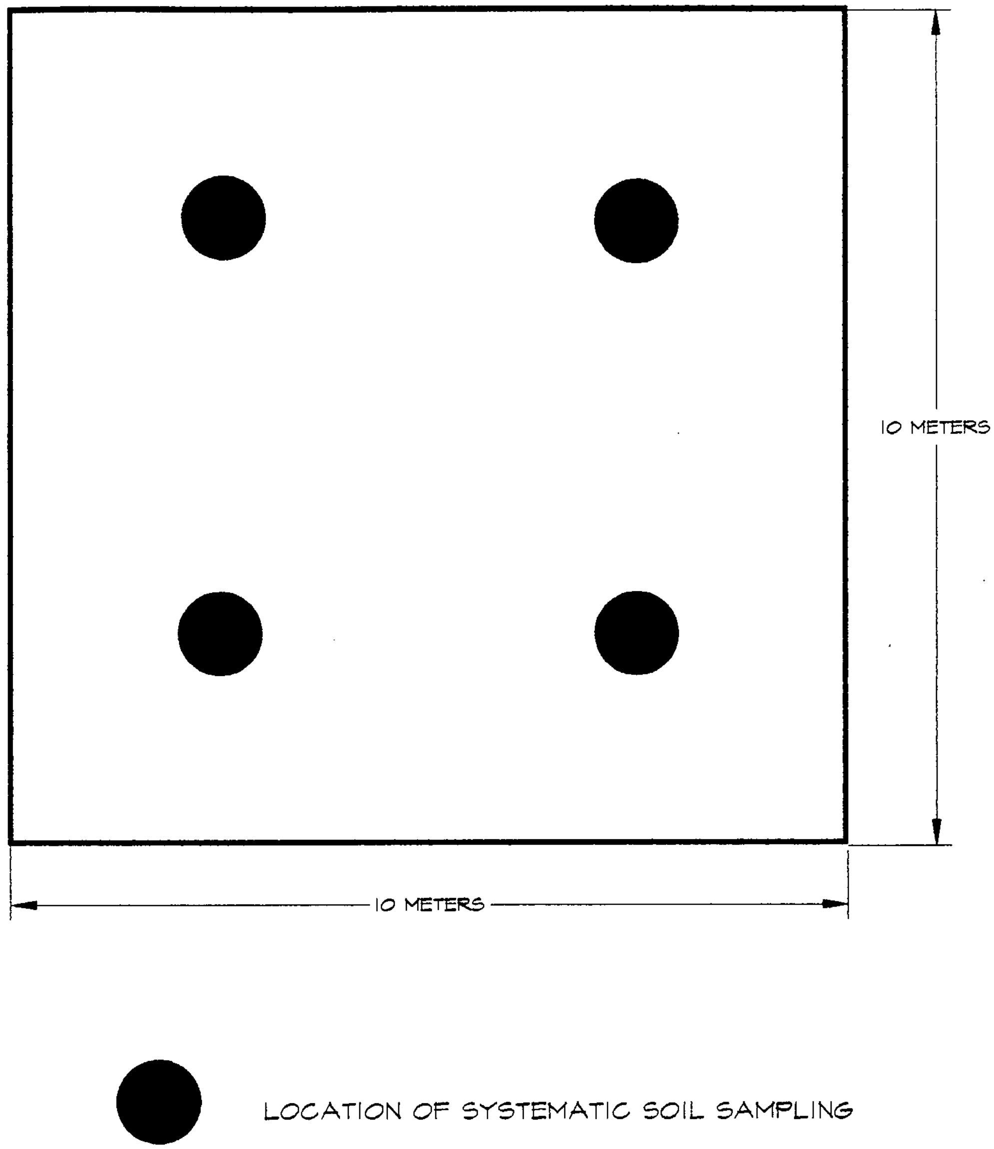

FIGURE A-3.3-2
STANDARD SAMPLING PATTERN FOR
SYSTEMATIC SURVEY OF SOIL

4.0 PLACEMENT METHODS

4.1 Scrap and Debris

The scrap and debris will have a maximum dimension of 20 feet and a maximum volume of 30 cubic feet. Scrap exceeding these limits will be reduced to within the acceptable limits by breaking, cutting or other approved methods. Empty drums, tanks or other objects having a hollow volume greater than five cubic feet will be reduced in volume by at least 70 percent. If volume reduction is not feasible, openings will be made in the object to allow soils, tailings and/or other approved materials to enter the object at the time of covering on the tailings cells. The scrap, after having been reduced in dimension and volume, if required, will be placed on the tailings cells as directed by the QC officer.

Any scrap placed will be spread across the top of the tailings cells to avoid nesting and to reduce the volume of voids present in the disposed mass. Stockpiled soils, contaminated soils, tailings and/or other approved materials will be placed over and into the scrap in sufficient amount to fill the voids between the large pieces and the volume within the hollow pieces to form a coherent mass. It is recognized that some voids will remain because of the scrap volume reduction specified, and because of practical limitations of these procedures. Reasonable effort will be made to fill the voids. The approval of the Site Manager or a designated representative will be required for the use of materials other than stockpiled soils, contaminated soils or tailings for the purpose of filling voids.

4.2 Contaminated Soils and Raffinate Crystals

The various materials will not be concentrated in thick deposits on top of the tailings, but will be spread over the working surface as much as possible to provide relatively uniform settlement and consolidation characteristics of the cleanup materials.

4.3 Compaction Requirements

The scrap, contaminated soils and other materials for the first lift will be placed over the existing tailings surface to a depth of up to four feet thick in a bridging lift to allow access for placing and compacting equipment. The first lift will be compacted by the tracking of heavy equipment, such as a Caterpillar D6 Dozer (or equivalent), at least four times prior to the placement of a subsequent lift. Subsequent layers will not exceed two feet and will be compacted to the same requirements.

During construction, the compaction requirements for the crystals will be reevaluated based on field conditions and modified by the Site Manager or a designated representative, with the agreement of the Executive Secretary.

The contaminated soils and other cleanup materials after the bridging lift will be compacted to at least 80 percent of standard Proctor maximum density (ASTM D-698).

5.0 RECLAMATION CAP - CELLS 1, 2, 3, 4A AND 4B

5.1 Earth Cover

A multi-layered earthen cover will be placed over tailings Cells 2, 3, 4A and 4B and a portion of Cell 1 used for disposal of contaminated materials (the Cell1 Tailings Area). The general grading plan is shown on Drawing A-5.1-1. Reclamation cover cross-sections are shown on Drawings A-5.1-2 and A-5.1-3.

5.2 Materials

5.2.1 Physical Properties

The physical properties of materials for use as cover soils will meet the following:

Random Fill (Platform Fill and Frost Barrier)
These materials will be mixtures of clayey sands and silts with random amounts of gravel and rock size material. In the initial bridging lift of the platform fill, rock sizes of up to 2/3 of the thickness of the lift will be allowed. On all other random fill lifts, rock sizes will be limited to 2/3 of the lift thickness, with at least 30 percent of the material finer than 40 sieve. For that portion passing the No. 40 sieve, these soils will classify as CL, SC, MC or SM materials under the Unified Soil Classification System. Oversized material will be controlled through selective excavation at the stockpiles and through the utilization of a grader, bulldozer or backhoe to cull oversize from the fill.

Clay Layer Materials

Clays will have at least 40 percent passing the No. 200 sieve. The minimum liquid limit of these soils will be 25 and the plasticity index will be 15 or greater. These soils will classify as CL, SC or CH materials under the Unified Soil Classification System.

LEGEND

5582.6	EXISTING SPOT ELEVATION
5612	ELEVATION OF TOP OF COVER
5612	ELEVATION OF TOP OF COVER CELL 4B
~5560~	EXISTING GROUND CONTOUR

NOTES

1. THE COVER WILL MEET THE GROUND WITH A DOWNWARD SIDE SLOPE OF 5H:1V.
2. ELEVATION OF THE BERMS SHOULD BE ADJUSTED TO MATCH WITH THOSE OF THE COVER.
3. A PORTION OF CELL 1-I WILL BE USED FOR PERMENANT STORAGE OF CONTAMINATED MATERIALS UPON FINAL SITE DECOMMISSIONING. (3)
4. TOPOGRAPHY BY KLH ENGINEERING FROM AERIAL PHOTOGRAPHY DATED AUGUST 23, 1993. CONTOUR INTERVAL IS 2 FT.
5. SEE FIGURES A-5.1-2 AND A-5.1-3 FOR CROSS SECTIONS AND DETAILS.
6. EXISTING GROUND SURFACES SHALL BE REGRADED TO CONSTRUCT THE COVER WITH A FINAL SURFACE THAT IS CONSISTENT WITH THE RECLAMATION COVER GRADING PLAN.

5.2.2 Borrow Sources

The sources for soils for the cover materials are as follows:

1. Random Fill (Platform and Frost Barrier) - stockpiles from previous cell construction activities currently located to the east and west of the tailing facilities.

2. Clay - will be from suitable materials stockpiled on site during cell construction or will be imported from borrow areas located in Section 16, T38S, R22E, SLM.

3. Rock Armor - will be produced through screening of alluvial gravels located in deposits 1 mile north of Blanding, Utah; 7 miles north of the Mill site.

5.3 Cover Construction

5.3.1 General

Placement of cover materials will be based on a schedule determined by analysis of settlement data, piezometer data and equipment mobility considerations. Settlement plates and piezometers will be installed and monitored in accordance with Section 5.4 of these Plans and Specifications.

5.3.2 Placement and Compaction

5.3.2.1 Methods

Platform Fill

An initial lift of 3 to 4 feet of random fill will be placed over the tailings surface to form a stable working platform for subsequent controlled fill placement. This initial lift will be placed by pushing random fill material or contaminated materials across the tailings in increments, slowly enough that_the underlying tailings are displaced as little as possible. Compaction of the initial lift will be limited to what the weight of the placement equipment provides. The maximum rock size, as far as practicable, in the initial lift is 2/3 of the lift thickness. Placement of fill will be monitored by a qualified individual with the authority to stop work and reject material being placed. The top surface (top 1.0 feet) of the platform fill will be compacted to 90% maximum dry density per ASTM D 698.

Frost Barrier Fill

Frost barrier fill will be placed above the clay cover in 12- inch lifts, with particle size limited to 2/3 of the lift thickness. Frost barrier material will come from the excavation of random fill stockpiles, If oversized material is observed during the excavation of fill material it will be removed as far as practicable before it is placed in the fill.

In all layers of the cover the distribution and gradation of the materials throughout each fill layer will be such that the fill will, as far as practicable, be free of lenses, pockets, streaks or layers of material differing substantially in texture, gradation or moisture content from the surrounding material. Nesting of oversized material will be controlled through selective excavation of stockpiled material, observation of placement by a qualified individual with authority to stop work and reject material being placed and by culling oversized material from the fill utilizing a grader. Successive loads of material will be placed on the fill so as to produce the best practical distribution of material.

If the compacted surface of any layer of fill is too dry or smooth to bond properly with the layer of material to be placed thereon, it will be moistened and/or reworked with a harrow, scarifier, or other suitable equipment to a sufficient depth to provide relatively uniform moisture content and a satisfactory bonding surface before the next succeeding layer of earthfill is placed. If the compacted surface of any layer of earthfill in-place is too wet, due to precipitation, for proper compaction of the earthfill material to be placed thereon, it will be reworked with harrow, scarifier or other suitable equipment to reduce the moisture content to the required level shown in Table 5.3.2.1-1. It will then be recompacted to the earthfill requirements.

No material will be placed when either the materials, or the underlying material, is frozen or when ambient temperatures do not permit the placement or compaction of the materials to the specified density, without developing frost lenses in the fill.

5.3.2.2 Moisture and Density Control

As far as practicable, the materials will be brought to the proper moisture content before placement on tailings, or moisture will be added to the material by sprinkling on the earthfill. Each layer of the fill will be conditioned so that the moisture content is uniform throughout the layer prior to and during compaction. The moisture content of the compacted fill will be within the limits of standard optimum moisture content as shown in Table 5.3.2.1-1. Material that is too dry or too wet to permit bonding of layers during compaction will be rejected and will be reworked until the moisture content is within the specified limits. Reworking may include removal, re-harrowing, reconditioning, rerolling, or combinations of these procedures.

Density control of compacted soil will be such that the compacted material represented by samples having a dry density less than the values shown in Table 5.3.2.1-1 will be rejected. Such rejected material will be reworked as necessary and rerolled until a dry density equal to or greater than the percent of its standard Proctor maximum density shown in Table 5.3.2.1-1.

To determine that the moisture content and dry density requirements of the compacted fill are being met, field and laboratory tests will be made at specified intervals taken from the compacted fills as specified in Section 7.4, "Frequency of Quality Control Tests."

5.4 Monitoring Cover Settlement

5.4.1 Temporary Settlement Plates

5.4.1.1 General

Temporary settlement plates will be installed in the tailings Cells. At the time of cell closure, a monitoring program will be proposed to the Executive Secretary. Data collected will be analyzed and the reclamation techniques and schedule adjusted accordingly.

5.4.1.2 Installation

At the time of cell closure or during the placement of interim cover temporary settlement plates will be installed. These temporary settlement plates will consist of a corrosion resistant steel plate 1/4 inch thick and two foot square to which a one inch diameter corrosion resistant monitor pipe has been welded. The one inch monitor pipe will be surrounded by a three inch diameter guard pipe which will not be attached to the base plate.

The installation will consist of leveling an area on the existing surface of the tailings, and placing the base plate directly on the tailings. A minimum three feet of initial soil or tailings cover will be placed on the base plate for a minimum radial distance of five feet from the pipe.

5.4.1.3 Monitoring Settlement Plates

Monitoring of settlement plates will be in accordance with the program submitted to and approved by the DRC. Settlement observations will be made in accordance with Quality Control Procedure QC-16-WM, "Monitoring of Temporary Settlement Plates."

TABLE A-5.3.2.1-1

Placement and Compaction Criteria
Reclamation Cover Materials

Cover Layer	Maximum Lift Thickness	Per Cent Compaction	Allowable Placement Moisture Content from Optimum Moisture Content
Platform Fill	3 Feet Bridging Lift*	80	
	1 Foot	90	± 2
Clay Layer	1 Foot	95	0 to + 3
Frost Barrier	2 Feet	95	± 2
Riprap			
Top of Tails	6 Inches		
Slope	8 Inches		

Note:
* Compaction of the bridging lift is dependent on stability of fill and equipment used
Percent Compaction is based on standard Proctor dry density (ASTM D-698).

Optimum moisture content of a soil will be determined by ASTM D-2216 or D-4643 methods.

6.0 ROCK PROTECTION

6.1 General

The side slopes of the reclaimed cover will be protected by rock surfacing. Drawings 5.1-1, 5.1-2, and 5.1-3 show the location of rock protection with the size, thickness and gradation requirements for the various side slopes.

A riprap layer was designed for erosion protection of the tailings soil cover. According to NRC guidance, the design must be adequate to protect the soil/tailings against exposure and erosion for 200 to 1,000 years (NRC, 1990). Currently, there is no standard industry practice for stabilizing tailings for 1,000 years. However, by treating the embankment slopes as wide channels, the hydraulic design principles and practices associated with channel design were used to design stable slopes that will not erode. Thus, a conservative design based on NRC guidelines was developed. Engineering details and calculations are summarized in the Tailings Cover Design report (Appendix D).

Riprap cover specifications for the top and side slopes were determined separately as the side slopes are much steeper than the slope of the top of the cover. The size and thickness of the riprap on the top of the cover was calculated using the Safety Factor Method (NUREG/CR-4651, 1987), while the Stephenson Method (NUREG/CR-4651, 1987) was used for the side slopes. These methodologies were chosen based on NRC recommendations (1990).

By the Safety Factor Method, riprap dimensions for the top slope were calculated in order to achieve a slope "safety factor" of 1.1. For the top of the soil cover, with a slope of 0.2 percent, the Safety Factor Method indicated a median diameter (D_{50}) riprap of 0.28 inches is required to stabilize the top slope. However, this dimension must be modified based on the long-term durability of the specific rock type to be used in construction. The suitability of rock to be used as a protective cover has been assessed by laboratory tests to determine the physical characteristics of the rocks. The gravels sourced from pits located north of Blanding require an oversizing factor of 9.35%. Therefore, riprap created from this source should have a D_{50} size of at least 0.306 inches and should have an overall layer thickness of at least three inches on the top of the cover. From a practical construction standpoint the minimum rock layer thickness may be up to six (6) inches.

Riprap dimensions for the side slopes were calculated using Stephenson Method equations. The side slopes of the cover are designed at 5H:1V. At this slope, Stephenson's Method indicated the unmodified riprap D_{50} of 3.24 inches is required. Again assuming that the gravel from north of Blanding will be used, the modified D_{50} size of the riprap should be at least 3.54 inches with an overall layer thickness of at least 8 inches.

Riprap bedding should be placed between the random fill and the riprap on the side slopes. The bedding should consist of medium sand, and should be placed with a minimum layer thickness of 6 inches.

6.2 Materials

Materials utilized for riprap applications will meet the following specifications:

Material	D_{50} Size	D_{100} Size	Layer Thickness
Top Surface Riprap	0.3"	0.6"	6"
Slope Surface Bedding	No. 40 Sieve	3”	6”
Slope Surface Riprap	3.5"	7"	8"
Toe Apron Riprap	6.4"	12"	24"

Riprap will be supplied to the project from gravel sources located north of the project site. Riprap will be a screened product.

Riprap quality will be evaluated by methods presented in NUREG/1623 Design of Erosion Protection for Long-Term Stabilization Size adjustment will be made in the riprap for materials not meeting the quality criteria.

6.3 Placement

Riprap and bedding material will be hauled to the reclaimed surfaces and placed on the surfaces using belly dump highway trucks and road graders. Riprap and bedding will be dumped by trucks in windrows and the grader will spread the riprap in a manner to minimize segregation of the material. Depth of placement will be controlled through the establishment of grade stakes placed on a 200 x 200 foot grid on the top of the cells and by a 100 x 100 foot grid on the cell slopes. Physical checks of riprap and bedding depth will be accomplished through the use of hand dug test pits at the center of each grid in addition to monitoring the depth indicated on the grade stakes. Placement of the riprap and bedding will avoid accumulation of riprap or bedding sizes less than the minimum D_{50} size and nesting of the larger sized rock. The riprap and bedding layer will be compacted by at least two passes by a D-7 Dozer (or equivalent) in order to key the rock for stability.

7.0 QUALITY CONTROL/QUALITY ASSURANCE

7.1 Quality Plan

A Quality Plan has been developed for construction activities at the Mill. The Quality Plan includes the following:

1. QC/QA Definitions, Methodology and Activities.

2. Organizational Structure.
3. Surveys, Inspections, Sampling and Testing.
4. Changes and Corrective Actions.
5. Documentation Requirements.
6. Quality Control Procedures.

7.2 Implementation

The Quality Plan will be implemented upon initiation of reclamation work.

7.3 Quality Control Procedures

Quality control procedures have been developed for reclamation and are presented in Attachment B of this Reclamation Plan. Procedures will be used for all testing, sampling and inspection functions.

7.4 Frequency of Quality Control Tests

The frequency of the quality control tests for earthwork will be as follows:

1. The frequency of the field density and moisture tests will be not less than one test per 1,000 cubic yards (CY) of compacted contaminated material placed and one test per 500 CY of compacted random fill, radon barrier or frost barrier. A minimum of two tests will be taken for each day that an applicable amount of fill is placed in excess of 150 CY. A minimum of one test per lift and at least one test for every full shift of compaction operations will be taken.

   Field density/moisture tests will be performed utilizing a nuclear density gauge (ASTM D-2922 density and ASTM D-3017 moisture content). Correlation tests will be

performed at a rate of one for every five nuclear gauge tests for compacted contaminated materials (one
per 2,500 CY placed) and one for every ten nuclear gauge tests for other compacted materials (one per 5,000 CY of material placed). Correlation tests will be sand cone tests (ASTM D-1556) for density determination and oven drying method (ASTM D-2216) for moisture determination.

2. Gradation and classification testing will be performed at a minimum of one test per 2,000 CY of upper platform fill and frost barrier placed. A minimum of one test will be performed for each 1,000 CY of radon barrier material placed. For all materials other than random fill and contaminated materials, at least one gradation test will be run for each day of significant material placement (in excess of 150 CY).

3. Atterberg limits will be determined on materials being placed as radon barrier. Radon barrier material will be tested at a rate of at least once each day of significant material placement (in excess of 150 CY). Samples should be randomly selected.

4. Prior to the start of field compaction operations, appropriate laboratory compaction curves will be obtained for the range of materials to be placed. During construction, one point Proctor tests will be performed at a frequency of one test per every five field density tests (one test per 2,500 CY placed). Laboratory compaction curves (based on complete Proctor tests) will be obtained at a frequency of approximately one for every 10 to 15 field density tests (one lab Proctor test per 5,000 CY to 7,500 CY placed), depending on the variability of materials being placed.

5. For riprap and bedding materials, each load of material will be visually checked against standard piles for gradation prior to transport to the tailings piles.

Prior to delivery of any riprap materials to the site rock durability tests will be performed for each gradation to be used. Test series for riprap durability will include specific gravity, absorption, sodium soundness and LA abrasion. During construction
gradations will be performed for each type of riprap and bedding when approximately one-third (1/3) and two-thirds (2/3) of the total volume of each type have been produced or delivered. In addition, test series for rock durability will be performed on any riprap material at this same time. For any type of riprap where the volume is greater than 30,000 CY, a test series and gradations will be performed for each additional 10,000 CY of riprap produced or delivered.

LIST OF TABLES

LIST OF FIGURES

LIST OF APPENDICES

1.0 INTRODUCTION

This report presents the design of a monolithic evapotranspiration (ET) cover for the tailings management cells at the Energy Fuels Resources (USA) Inc. (EFRI) White Mesa Uranium Mill (Mill). The Mill is located approximately 6 miles south of Blanding, in San Juan County, Utah. The Mill site includes a conventional acid leach process mill, associated support facilities, and lined tailings management cells. The tailings management cells are located south of the Mill and comprise the following:

- Cell 1 – 55 acres, used for the evaporation of process solutions
- Cell 2 – 65 acres, used for storage of barren tailings sands (which has been filled with tailings sands and covered with a minimum of approximately 3 feet of interim cover across the cell)
- Cell 3 – 70 acres, used for storage of barren tailings sands (which have been partially covered with a minimum of approximately 3 feet interim cover across the majority of the cell, except the center of the cell which is currently receiving mill waste)
- Cell 4A – 40 acres, used for storage of barren tailings sands and evaporation of process solutions
- Cell 4B – 40 acres, currently being used for evaporation of process solutions

The cover design in this report has been written assuming tailings management Cells 2, 3, 4A, and 4B receive tailings to the maximum permitted tailings elevations. Cell 2 is full and partially reclaimed. Cell 3 was used for tailings storage, but is currently only receiving mill waste. Cell 3 is partially full and partially reclaimed. Cell 4A is the only cell currently receiving tailings and is partially full. Cell 4B is used for evaporation of process solutions and has not been used for storage of tailings. The tailings cover design assumes Cell 4B will be used for future tailings storage.

1.1 Scope of Report

A previous “Tailings Cover Design” report for the White Mesa Mill was prepared by Titan Environmental Corporation (Titan, 1996), and presented design criteria for a multi-layered cover system. This design report was included as Appendix D of the Reclamation Plan, Revision 4.0 (Denison, 2009) and previous versions of the Reclamation Plan.

An Updated Tailings Cover Design Report (MWH, 2011) was prepared to replace the Titan (1996) report as Appendix D to the Reclamation Plan, Revision 5.0 (Denison, 2011). The 2011 report provided design criteria for a proposed monolithic ET cover system for all the tailings management cells. This report is an update to the 2011 report and is provided as Appendix A to Reclamation Plan, Revision 5.1. The revised report includes subsequent cover design updates provided in EFRI responses to interrogatories and review comments (Denison, 2012; EFRI, 2012a; EFRI, 2015a) from Utah Department of Environmental Quality (UDEQ), Division of Waste Management and Radiation Control (DWMRC) on Reclamation Plan, Revision 5. Prior to 2015, the DWMRC was two separate divisions of UDEQ, the Division of Radiation Control and the Division of Solid and Hazardous Waste.

This report provides detailed summaries and results of the analyses conducted to evaluate the long-term stability of the tailings reclamation cover including evaluations of freeze/thaw, radon attenuation, biointrusion, infiltration, slope stability, settlement, liquefaction, erosional stability, and dewatering. This report also presents plans for final cover verification, vegetation, and long-term settlement monitoring.

1.2 Updates from 1996 Cover Design

The cover system presented in Titan (1996) was 6 feet thick, and consisted of random fill and clay, compacted to 95 percent of maximum dry density. The cover system consisted of the following materials, outlined below by individual layers and thicknesses from top to bottom:

- 3 in (7.6 cm) Erosion Protection Layer (gravel)
- 2 ft (61 cm) Radon Attenuation Layer (random fill)
- 1 ft (30.5) Radon Attenuation Layer (compacted clay)
- Minimum 3 ft (91.4 cm) Radon Attenuation and Grading Layer (random fill)

This cover design was presented in the Reclamation Plan, Revision 4.0 (Denison, 2009) for Cells 1, 2, 3, and 4A. Titan (1996) analyzed the proposed cover with respect to radon flux attenuation, infiltration, effects of free/thaw, erosion protection, and static and pseudostatic slope stability.

A conceptual ET cover design was proposed by EFRI for the White Mesa Mill disposal cells in the Infiltration and Contaminant Transport Modeling (ICTM) reports (MWH 2007 and 2010) submitted to the DWMRC to fulfill the White Mesa Mill's Ground Water Discharge Permit No. UGW370004. It was intended that the final design of the tailings cover would be completed as part of an updated tailings cover design report.

EFRI stated their intent to submit an ET cover design as part of their license renewal in a meeting with DWMRC on October 5, 2010 after review of the DWMRC Reclamation Plan, Version 4.0 Interrogatories – Round 1 (DRC, 2010). The proposed conceptual ET cover design was provided to DWMRC on October 7, 2010 and was essentially the same as presented in the 2010 ICTM report (MWH, 2010). The ET cover proposed and evaluated as described in this Updated Tailings Design Report (9.5 to 10.5 feet thick) is shown in Figure 1-1 and consists of the following materials outlined below by individual layers and thicknesses from top to bottom:

- Layer 4 - 0.5 ft (15 cm) thick Erosion Protection Layer (gravel-admixture or topsoil)
- Layer 3 - 3.5 ft (107 cm) thick Growth Medium Layer acting as a Water Storage/Biointrusion/Frost Protection/Secondary Radon Attenuation Layer (loam to sandy clay)
- Layer 2 – 3.0 to 4.0 ft (91 to 122 cm) thick Compacted Cover acting as the Primary Radon Attenuation Layer (highly compacted loam to sandy clay)
- Layer 1 - 2.5 ft (76 cm) thick (minimum) Interim Fill Layer acting as a Secondary Radon Attenuation and Grading Layer (loam to sandy clay)

The loam to sandy clay soil is the same material referred to in Titan (1996) as random/platform fill. This material is stockpiled at the site.

This Updated Tailings Design Report provides the results of additional laboratory testing and analyses for the monolithic ET cover design, including radon flux attenuation, infiltration, effects of freeze/thaw, erosion protection, and static and pseudostatic slope stability. This report also presents analyses not performed for the Titan (1996) design, including biointrusion, tailings dewatering, liquefaction, and settlement.

1.3 Limitations

The analyses presented in this report use information from reports prepared by others that have been provided by EFRI, and MWH's experience with the White Mesa Mill site and other similar uranium mill sites. The analyses are limited by the information available but are supplemented by MWH's experience with the White Mesa Mill and other similar uranium mill sites. In the event that there are any changes in the nature, design, or characteristics of the project, or if additional data are obtained, conclusions and recommendations contained in the report will need to be re-evaluated by MWH in light of the proposed changes or additional information obtained.

MWH warrants that services were performed within the limits prescribed by EFRI with the usual thoroughness and competence of the engineering profession. No other warranty or representation, either expressed or implied, is included or intended in our technical documents.

TITLE: ET COVER PROFILE

MWH

DATE: AUG 2016

FIGURE 1-1

FILE NAME: 1009740 WM ET COVR

2.0 SITE CONDITIONS

2.1 Location

The White Mesa Uranium Mill is located in San Juan County in southeastern Utah, approximately 6 miles south of Blanding, Utah. The site is located on White Mesa, a flat area bounded on the east by Corral Canyon, to the west by Westwater Creek and to the south by Cottonwood Canyon. A site location map is shown on Figure 2-1. The Mill is located at an elevation of approximately 5,600 ft above mean sea level. The EFRI facilities consist of a uranium processing mill and five lined tailings management cells located within an approximately 686-acre restricted area. Total land holdings are approximately 5,415 acres (Denison, 2011).

2.2 Climate and Vegetation

2.2.1 Climate

The regional climate of the Blanding area is semiarid with an average annual precipitation of 13.3 inches (Denison, 2011). Most precipitation is in the form of rain, with snowfall accounting for about one quarter of the annual total precipitation. There are two separate rainfall seasons in the region, a late summer season when monsoonal moisture from the Gulf of Mexico produces thunderstorms, and a second during the winter season related to fronts from the Pacific. The average annual Class A pan evaporation is 68 inches, with the largest monthly evaporation rate typically occurring in July (Denison, 2011).

The mean annual temperature for Blanding, Utah is 52°F, based on the period of 1971-2000. January is typically the coldest month, with a mean monthly temperature of about 30°F. July is generally the warmest month, with a mean monthly temperature of 76°F. Daily ranges in temperatures are typically large.

As an element of the pre-construction baseline study and ongoing monitoring programs, the Mill operates an onsite meteorological station, which became operational in early 1977 and continues to operate. Additional information on climatic conditions is presented in the Reclamation Plan, Revision 5.1.

2.2.2 Vegetation

As described in Denison (2011), the natural vegetation near the site is characterized by pinyon-juniper woodland intergrading with big sagebrush (*Artemisia tridentata*) communities. The understory of this community, which is usually quite open, is composed of grasses, forbs, and shrubs that are also found in the big sagebrush communities. Based on work completed by Dames & Moore in the 1978 Environmental Report (Dames & Moore, 1978), no designated or proposed endangered plant species occur on or near the Mill site. A complete discussion of flora and fauna present in the vicinity of the Mill site is provided in Dames & Moore (1978).

In June 2012, the area surrounding the Mill site was surveyed for plant composition to supplement data presented in Dames & Moore (1978). Survey results confirmed that two principal plant community types in the vicinity of the Mill site. These plant communities are Big Sagebrush shrubland and Juniper woodland. In addition to these two principal plant community types, there are a number of disturbed areas in different stages of successional development. These areas reflect past disturbances such as sagebrush removal (chaining and plowing) and seeding and intense grazing, as evidenced by a complete lack of any understory species in some areas. The vegetation survey conducted in 2012 provides information of species that exist on the Mill site and their relative importance in terms of plant cover. All areas surveyed in 2012 show that big sagebrush (*Artemisia tridentata*) is the dominant species and subdominants are either broom snakeweed (*Gutierrezia sarothroae*) or galleta (*Hilaria jamesii*). Additional discussion on this survey is provided in Appendix D.

2.3 Geology and Seismicity

The White Mesa Mill is located within the Blanding Basin of the Colorado Plateau physiographic province in southeastern Utah. The site is underlain by unconsolidated alluvium overlying sedimentary bedrock, consisting primarily of sandstone and shale. The unconsolidated deposits are primarily eolian silt and sand and range from 1 to 30 ft thick (these deposits have been removed where the tailings cells are located). The bedrock underlying the site is relatively undeformed, with horizontally oriented bedding (generally dips are less than 3 degrees). Cretaceous Dakota Sandstone and Burro Canyon Formation are at or near the surface at the site; these sandstone units have a combined thickness of 100 to 140 ft at the site. Beneath the Burro Canyon Formation is the Jurassic Morrison Formation, which is primarily shale. The Brushy Basin Member is the uppermost member of the Morrison Formation and is composed primarily of bentonitic mudstones, siltstones, and claystones. Beneath the Brushy Basin Member are the Westwater Canyon, Recapture, and Salt Wash members of the Morrison Formation. Beneath the Morrison Formation lies the Middle to Late Jurassic San Rafael group, and the Late Triassic to Jurassic Glen Canyon Group. Additional details of the geologic setting are included in the Reclamation Plan, Revision 5.1.

The seismicity of the Colorado Plateau is characterized as small to moderate magnitude with a low to moderate rate of widely-distributed earthquakes (Wong and Humphrey, 1989). The Mill area is located within a relatively tectonically stable portion of the Colorado Plateau, characterized by relatively sparse concentrations of earthquake events. Most of the larger seismic events in the Colorado Plateau have occurred along its margins rather than in the interior central region. Based on the region's seismic history, the probability of a major damaging earthquake occurring at or near the Mill site is low. Additional information on the seismotectonics of the Mill site and vicinity is provided in the Reclamation Plan, Revision 5.1.

Several site-specific seismic studies have been performed for the Mill site (UMETCO, 1988; Tetra Tech, 2006; Tetra Tech, 2010, MWH, 2015b). The most recent study (MWH, 2015b) was performed to provide additional information for design of the tailings reclamation cover system. This study concluded that the maximum horizontal acceleration value at the Mill site for a seismic event associated with an average return period of 10,000 years is 0.15g. Based on this maximum horizontal acceleration, a pseudo-static coefficient of 0.10g was used for seismic stability analyses of the reclaimed tailings impoundments (presented in Appendix E).

2.4 Hydrogeology

Groundwater beneath the site is first encountered as a perched zone within the Burro Canyon Formation. The low-permeability Brushy Basin Member of the Morrison Formation acts as an aquitard and forms the base of this perched zone. The saturated thickness of the perched zone ranges from less than 5 ft to as much as 82 ft beneath the site, assuming the base of the Burro Canyon Formation is the base of the perched zone. The water table of the perched zone was 13 to 116 ft below ground surface (bgs) at the facility in 2007 (MWH, 2010), and is shallowest near the wildlife ponds east of the Mill and tailings management cells. Groundwater within the perched zone generally flows south to southwest beneath the site. The Reclamation Plan, Revision 5.1 and MWH (2010) provide more details of the perched zone hydrogeology.

Aquifers of the Entrada sandstone and Navajo sandstone are located approximately 1,200 ft bgs, and are considered one aquifer for purposes of this report. The Navajo/Entrada Aquifer is capable of yielding significant quantities of water to wells (hundreds of gallons per minute (gpm)). Water in the Entrada/Navajo Aquifer is artesian, and rises approximately 800 ft above the base of the overlying Summerville Formation resulting in static water levels 390 to 500 ft below the ground surface (Denison, 2011). The Reclamation Plan, Revision 5.1 provides more information regarding the aquifer hydrogeology.

2.5 Reclamation Materials

The following sections summarize the characteristics of the tailings, the cover borrow materials to be used in reclamation of the tailings disposal cells, and the potential erosion protection materials.

2.5.1 Tailings Characterization

Geotechnical and radiological data on tailings were previously collected and data applicable to the cover design are included in Appendix A.1. This data was previously presented in Attachments D and E of the Reclamation Plan, Version 4.0 (Denison, 2009). Geotechnical laboratory testing was conducted by Western Colorado Testing, Inc. (1999b) on the tailings and included specific gravity, standard Proctor, Atterberg limits, and gradation (including hydrometer). Testing was conducted on four samples of tailings from Cell 2 and two samples of tailings from Cell 3. Rogers & Associates Engineering Corp. (1988) measured radium-226 activity concentration and the radon emanation coefficient on one tailings sample.

An additional investigation of the tailings in Cells 2 and 3 was performed in 2013 and results were presented in the Tailings Data Analysis Report (MWH, 2015a). This investigation was performed to satisfy DWMRC's request that EFRI collect site-specific tailings data to supplement previous investigations. The objectives of the investigation were to measure the physical properties of the tailings and characterize the stratigraphy of the tailings through Cone Penetration Test (CPT) soundings, direct push sampling, and geotechnical laboratory testing.

The geotechnical and radiological testing results for the tailings were used for the radon emanation modeling and the settlement and liquefaction analyses presented in this report.

2.5.2 Cover Borrow Material Characterization

Geotechnical and radiological data on potential cover materials were previously collected and data applicable to the cover design are included in Appendix A.1. Some of this data was previously presented in Attachment D of the Reclamation Plan, Version 4.0 (Denison, 2009) and in Titan (1996). Geotechnical laboratory testing of potential cover material (random fill) from on-site was conducted by Chen and Associates, Inc. (1978, 1979, and 1987), Geosyntec Consultants (2006), and Western Colorado Testing, Inc. (1999a). Geotechnical testing included in-situ moisture contents, specific gravity, standard Proctor, modified Proctor, Atterberg limits, gradation, and permeability. Radon diffusion coefficients of random fill samples collected from on-site stockpiles were measured by Rogers & Associates Engineering Corp. (1988). Geotechnical and radiological testing results were used for the radon emanation modeling and the settlement and liquefaction analysis presented in this report.

MWH conducted a field investigation at the Mill site on October 12, 2010 to supplement existing soils data and further evaluate the geotechnical properties of the potential cover material. Potential cover borrow material locations are shown on Figure 2-2. MWH visually evaluated all of the borrow locations and collected representative bulk samples from select locations. The bulk samples were sent to Advanced Terra Testing in Denver, Colorado for laboratory testing. Laboratory testing conducted on the collected samples included in-situ water contents, Atterberg limits, specific gravity, and gradation (including hydrometer). The laboratory testing results are summarized in Table 2-1 and provided in Appendix A.2.

An additional field investigation was conducted in April 2012 to supplement existing soils data and further evaluate the geotechnical properties of the potential cover material. Test pits were excavated into select on-site stockpiles and representative bulk samples were collected for laboratory testing. Laboratory testing included Atterberg limits, specific gravity, gradation, standard Proctor compaction, saturated hydraulic conductivity, and moisture retention. The test pit logs and laboratory testing logs are provided in Appendix A.3.

The volume of material available at each stockpile was estimated based on the 2010 and 2012 field investigations and is summarized in Table 2-1. The results from the cover borrow material characterization were used for the radon attenuation, settlement and liquefaction, and erosional stability cover design analyses presented in this report.

Table 2-1. Summary of Laboratory Test Results for Borrow Stockpiles and Estimated Volumes

Borrow Stockpile ID	Estimated Stockpile Volume[1] (cy)	Field Investigation Date	Material Description	Material USCS	Sample ID	Sample Depth (ft)	Gravimetric Water Content (%)	Atterberg Limits[2] LL/PL/PI (%)	Specific Gravity	Particle Size[3] % Gravel	% Sand	% Silt	% Clay	% Fines	Max. Notes:
1. Volumes estimated using 2009 topography and assuming a relatively flat bottom surface, except for stockpiles W5, W8 and W9. The volumes for stockpiles W8 and W9 were estimated by comparing the 2011 versus 2009 topography. The volume for stockpile W5 was estimated using a combination of both methods.
2. LL = Liquid Limit, PL = Plastic Limit, PI = Plasticity Index (PI = LL-PL)
3. Gravel = 4.75 mm to 75 mm, Sand = 0.075 mm to 4.75 mm, Fines: Silt = 0 .075 mm to 0.002 mm, Clay = less than 0.002 mm
4. Group B (broadly graded), Group U (uniformly graded), and Group F (fine textured) based on evaluation of gradations and Benson (2012)*.
5. From standard Proctor test

*Benson, C., 2012. Electronic communication from Craig Benson, University of Wisconsin-Madison, to Melanie Davis, MWH, regarding evaluation of gradations performed for potential cover soils for White Mesa, May 20.

2.5.3 Erosion Protection Material Characterization

Three rock sources were evaluated as potential material sources for use as erosion protection material (riprap and gravel) at the site. Samples were tested from the Cow Canyon pit located 15 miles south of the Mill, the Brown Canyon pit located 4 miles northeast of the Mill, and the North Pit located 1 mile northeast of Blanding. Samples from each quarry were tested for durability in general accordance with guidelines for long-term performance outlined by the US Nuclear Regulatory Commission (NRC). These guidelines are for rock to be used as erosion protection material on exposed surfaces and utilize a rock scoring value (Johnson, 2002). The following laboratory tests were performed, in accordance with U.S. Bureau of Reclamation (1987), to develop scoring criteria: specific gravity, absorption, sulfate soundness and L.A. Abrasion. Durability testing results are provided in Appendix K and were previously presented as Attachment H to the Reclamation Plan, Revision 4.0 (Denison, 2009). Table 2-2 summarizes the scoring of each potential rock source.

Table 2-2. NRC Riprap Scoring of Potential Rock Sources

Rock Source	Score (%)	Oversizing Required (%)
Cow Canyon Pit	87.61	None
Brown Canyon	60.98	19.02
North Pit	70.65	9.35

Based on information provided in Johnson (2002), areas defined as critical areas must meet a score of 65 percent or greater, and areas defined as non-critical areas must meet a score of 50 percent or higher. Critical areas include frequently saturated areas, all channels, poorly drained toes and aprons, control structures and energy dissipation areas. Non-critical areas include occasionally saturated areas, top slopes, side slopes, and well-drained toes and aprons. The scores calculated for each rock borrow site indicate that all three rock borrow sites would provide suitable rock for construction of the erosion protection along the embankment slopes. The Cow Canyon and North Pit sources would be used for the rock toe apron areas at the base of the toes of cell outslopes. Oversizing of both the Brown Canyon and North Pit rock would be required if used for construction. The Brown Canyon source would not be used to construct the rock toe apron areas at the base of the toes of cell outslopes.

3.0 REGULATORY CRITERIA

Prior to the State of Utah obtaining agreement state status in 2004, the tailings at the White Mesa Mill were regulated primarily by the NRC pursuant to 10 CFR 40, Appendix A, and the U.S. Environmental Protection Agency (EPA) under 10 CFR 61, Subparts A and W, which are administered by the State of Utah's Division of Air Quality. The State of Utah regulates the site according to rules and regulations presented in Title R313 – Environmental Quality, Radiation Control. These rules include, through reference, clarification, or exception, sections of 10 CFR 40 extending through Appendix A, and sections of 10 CFR Part 20. Additionally, the site is regulated under the site's approved Groundwater Discharge Permit (Permit No.UGW370004) (GWDP), which is administered by the State of Utah's Department of Environmental Quality.

NRC and EPA have a Memorandum of Understanding (MOU) that covers joint expectations under what was originally Subpart T of 40 CFR 61 (uranium mill tailings closure) and a generic MOU on elimination of dual regulation. The NRC regulations also incorporate other standards by reference that were promulgated by the EPA pursuant to the Uranium Mill Tailings Radiation Control Act (UMTRCA – 1978), and Section 112 of the Clean Air Act, as amended. Compliance with these regulations under the authority of the State of Utah is provided through UAC R313-24.

The reclamation cover design has been developed in accordance with UAC R313-24, 40 CFR Part 192, and Part I.D.8 of the GWDP. The following documents have also provided design guidance:

- Benson, C.H. W.H. Albright, D.O. Fratta, J.M. Tinjum, E. Kucukkirca, S.H. Lee, J. Scalia, P.D. Schlicht, and X. Wang, 2011. Engineered Covers for Waste Containment: Changes in Engineering Properties and Implications for Long-Term Performance Assessment (in four volumes). - U.S. Nuclear Regulatory Commission (NRC), 1990. "Final Staff Technical Position, Design of Erosion Protective Covers for Stabilization of Uranium Mill Tailings Sites," August.
- U.S. Nuclear Regulatory Commission (NRC), 2003. Standard Review Plan for the Review of a Reclamation Plan for Mill Tailings Sites under Title II of the Uranium Mill Tailings Radiation Control Act of 1978. NUREG-1620, Revision 1, June.

The key state and federal performance criteria for tailings cover design and reclamation include:

- Attenuate radon flux to a rate of 20 pCi/m^2-s, averaged over each entire cell
- Minimize infiltration into the reclaimed tailings cells
- Maintain a design life of up to 1,000 years and at least 200 years
- Provide long-term isolation of the tailings, including slope stability and geomorphic durability to withstand erosional forces of wind and runoff (up to the probable maximum precipitation event) as well as design to accommodate seismic events (up to the peak ground acceleration from the maximum credible earthquake)
- Designs to accommodate minimum reliance on active maintenance

Following reclamation of the Mill, a designated area of the site (including the tailings cells) will be transferred to the U.S. Department of Energy (DOE) for long-term care and maintenance and institutional control. Prior to transfer, the site closure and reclamation is reviewed by the NRC for compliance with applicable design criteria and guidance (specifically Appendix A of 10 CFR 40). The guidelines of reclamation review of a Title II facility are presented in NUREG-1620 (NRC, 2003).

4.0 COVER DESIGN

4.1 Drainage and Slopes

The slopes and drainage for the new ET cover have been modified from the 2009 Reclamation Plan (Denison, 2009) to incorporate the current ET cover system design. The slopes and drainage are to provide acceptable erosional stability under long-term conditions, represented by storms up to the Probable Maximum Precipitation (PMP) event. The evaluation of acceptable erosional stability was conducted according to current NRC guidelines documented in NRC (1990) and Johnson (2002). Results of analyses conducted for drainage and slopes are presented in Appendix G. The drainage and slopes are shown on the Drawings (Attachment A to the Reclamation Plan, Revision 5.1).

The drainage on the top surface of the ET cover at Cells 1, 2, and 3 is designed at a 0.5 percent slope, with portions of Cell 2 top surface at a 1 percent slope, and portions of Cells 4A and 4B top surfaces at 0.8 percent slope. The external side slopes of the embankments will be graded to 5:1 (horizontal:vertical). The overall site drainage around the reclaimed tailings cells is the same as presented in Denison (2011).

4.2 Cover System

The current cover system proposed for reclamation of the tailings cells is designed as a monolithic ET cover. This is different from the cover system proposed in Denison (2009). A monolithic ET cover is the preferred design in this environment to minimize infiltration, meet the radon emanation standard, minimize maintenance over the short and long term, and promote sustainability. The proposed cover design has been designed with sufficient thickness to protect against frost penetration, attenuate radon flux, minimize both plant root and burrowing animal intrusion, and provide adequate water storage capacity to minimize the rate of infiltration into the underlying tailings. Furthermore, the cover is designed to be stable under both static and anticipated seismic conditions, and to provide tailings isolation under long-term wind and water erosion conditions.

The ET cover system has a total thickness of 9.5 feet for Cells 1, 4A, and 4B, 10 feet for Cell 3, and 10.5 feet for Cell 2. The difference in cover thicknesses is based on the radon emanation analyses (Appendix C). The cover system will consist of the following materials listed below from top to bottom:

- Layer 4 - 0.5 ft (15 cm) thick Erosion Protection Layer (gravel-admixture or topsoil)
- Layer 3 - 3.5 ft (107 cm) thick Growth Medium Layer acting as a Water Storage/Biointrusion/Frost Protection/Secondary Radon Attenuation Layer (loam to sandy clay)
- Layer 2 – 3.0 to 4.0 ft (91 to 122 cm) thick Compacted Cover Layer acting as the Primary Radon Attenuation Layer (highly compacted loam to sandy clay)
- Layer 1 - 2.5 ft (76 cm) thick (minimum) Interim Fill Layer actin as a Secondary Radon Attenuation and Grading Layer (loam to sandy clay)

All the layers combined comprise the monolithic ET cover system. Layer 1 was placed in stages on Cell 2 and the majority of Cell 3 as interim cover. Layer 1 will be placed on the remaining area of Cell 3, all of the Cell 1 Disposal Area, and Cells 4A and 4B. It is assumed that this material was or will be dumped and minimally compacted by construction equipment to approximately 80 percent of standard Proctor density. Layer 1 will provide the platform for the remaining cover system and act as a secondary radon attenuation layer. Layer 2 will be compacted cover layer and act as the primary radon attenuation layer. It will be 3 - 4 feet thick (3 feet for Cells 1, 4A and 4B, 3.5 feet for Cell 3, and 4 feet for Cell 2) and compacted to 95 percent of standard Proctor density. Layer 3 will be the growth medium layer. Layer 3 will also act as a secondary radon attenuation layer and a protection layer for the primary radon attenuation layer (Layer 2). Layer 3 will be 3.5 feet thick and placed at 85 percent of standard Proctor density to optimize water storage and rooting characteristics for plant growth. Layer 4 will be a 0.5-foot thick erosion protection layer. This layer will consist of topsoil in areas where the cover is sloped at 0.5 percent and topsoil-gravel admixture in areas where the cover is sloped at 1 percent. The topsoil-gravel admixture will consist of topsoil (75 percent) mixed with 1-inch minus gravel (25 percent).

4.3 Freeze/Thaw

Titan (1996) included a freeze/thaw analysis for the reclamation cover design. Updates to these analyses were provided in Denison (2011) and Denison (2012). These updates reflect modifications to the proposed cover to incorporate an ET cover, a revised grading design, and results of cover material testing conducted in 2010. The 2012 update also included revisions to address review comments from DWMRC on Reclamation Plan, Revision 5.0 (DRC, 2012a). The analyses provided in Denison (2012) are included as Appendix B. The updated calculations of frost penetration at the site were performed with the computer program ModBerg (CRREL), which uses a built-in weather database, as well as user-defined soil parameters.

The freeze/thaw calculations estimate the total depth of frost penetration for the cover system as 32 inches (2.67 ft). The frost penetration depth is not anticipated to exceed the depth of Layers 3 and 4 of the cover system (combined depth of 4 ft). The physical and hydraulic properties of these cover system layers after construction are expected to be close to long-term properties from pedogenic processes, such that post-construction changes due to freeze/thaw should be minimal. A complete description of the freeze/thaw analyses conducted for the proposed cover system is presented in Appendix B.

4.4 Radon Attenuation

Titan (1996) included an analysis of radon attenuation for the reclamation cover design. Radon attenuation analyses were later conducted by MWH (2010) for the conceptual design of the monolithic ET cover. The results were presented in Appendix H of the Infiltration and Contaminant Transport Modeling Report (MWH, 2010). These analyses have been updated for this report to incorporate the revised design of the ET cover, changes to the grading plan, and additional geotechnical testing of material properties.

Emanation of radon-222 from the top surface of the proposed cover system for the tailings cells was calculated using the NRC RADON model (NRC, 1989). The model was used to confirm that the designed cover system can achieve the State of Utah's long-term radon emanation standard for uranium mill tailings (Utah Administrative Code, Rule 313-24), 20 picocuries per square meter per second (pCi/m^2-s). The analyses were conducted following the guidance presented in NRC publications NUREG/CR-3533 (NRC, 1984) and Regulatory Guide 3.64 (NRC, 1989). Results of the analyses show that the proposed cover system can reduce the rate of radon-222 emanation to less than 20 pCi/m^2-s, averaged over the entire area of each tailings cell. A complete description of the radon attenuation analyses conducted for the ET cover system is included in Appendix C.

4.5 Vegetation and Biointrusion

The plant species proposed for the cover system consist of native perennial grasses, forbs, and shrubs. The use of these species in reclamation of the tailing management cells provide a permanent or sustainable plant cover because of the highly adapted nature of these species to existing site conditions, their tolerance to environmental stresses such as drought, fire, and herbivory, and their ability to effectively reproduce over time. These species can coexist and fully utilize plant resources to minimize the establishment of invasive weeds and deep rooted woody species on the site. Once established, the proposed seed mixture produce a grass-forb-shrub community of highly adapted and productive species that can effectively compete with undesirable species. A complete discussion of cover vegetation is provided in Appendix D.

The proposed cover system is designed to minimize both plant root and burrowing animal intrusion through the use of thick layers of soil cover (total thickness 9.5 to 10.5 ft) in combination with a highly compacted layer placed at a depth that is below the expected rooting and burrowing depths of species that may inhabit the site. Root growth and animal burrowing into the highly compacted radon attenuation layer (beginning at a depth of 4 ft) will be restricted because of the high density of this material (compaction to 95 percent relative compaction based on the standard Proctor test). In addition, both root density and the size of roots decrease at a rapid rate with rooting depth, further limiting the potential for root growth into the compacted radon attenuation layer of the cover system. A complete discussion of the biointrusion evaluation through the ET cover is presented in Appendix D.

4.6 Infiltration

Infiltration modeling was conducted for the monolithic ET cover and a complete description of the analyses were provided in the ICTM Report (MWH, 2010). The modeling was updated to address DWMRC comments on the ICTM Report (DRC, 2012b; 2013) and to incorporate additional geotechnical and hydrologic data collected in as part of field investigations conducted in 2010 and 2012 for cover borrow material and in 2013 for in situ tailings. The updated infiltration modeling results were presented in EFRI (2012b) and EFRI (2015b). The evaluation of infiltration of precipitation through the cover system was evaluated with the computer program HYDRUS-1D (Simunek et al., 2009). The modeling used historical daily meteorological data for precipitation and evapotranspiration over a 57-year climate period, as well as assumptions that were either conservative or based on anticipated conditions. Given the flat nature of the cover (less than 1 percent slope), no run-on- or runoff-based processes were assumed to occur. As a result, precipitation applied to the cover surface was removed through evaporation or transpiration, retained in the soil profile as storage, or transmitted downward as infiltration.

The model-predicted average long-term water flux rate through the cover system is 2.3 mm/yr. Additional model scenarios were analyzed to evaluate the sensitivity of the soil properties, climate, and reduced vegetation parameters. The range of average long-term water flux rates for these scenarios varied from 1.9 to 8.6 mm/yr. The model-predicted water flux rates through the monolithic ET cover indicate that the available cover storage capacity should be sufficient to significantly reduce infiltration through the cover system.

4.7 Slope Stability Analysis

Static (long-term) and pseudo-static slope stability analyses were performed for two critical cross sections through the tailings embankments. The analyses were performed using limit equilibrium methods with the computer program SLOPE/W (Geo-Slope, 2007). A complete description of the input parameters and assumptions used in the analyses is provided in Appendix E. Material strength parameters used for the analyses were based on historical laboratory testing on tailings and clay materials (Advanced Terra Testing, 1996; Chen and Associates, 1987; D'Appolonia, 1982; and Western Colorado Testing, 1999b), laboratory testing conducted in 2010 and 2012 on potential cover borrow materials (see Attachment B of EFRI, 2012b), laboratory testing conducted in 2013 on tailings (MWH, 2015a) and typical published values.

The mean Peak Ground Acceleration (PGA) for reclaimed conditions is 0.15g based on the site specific PSHA (MWH, 2015b). This PGA represents the seismic loading from the Maximum Credible Earthquake (MCE). The seismic coefficient used for the pseudo static stability analysis was 0.10 g (equal to 2/3 of the PGA).

The calculated factors of safety range from 2.6 to 3.9 and 1.7 to 2.5 for static and pseudo-static loading conditions, respectively. The calculated factors of safety for both the long-term static condition and the pseudo-static condition exceed the required values of 1.5 and 1.1 respectively (NRC, 2003).

4.8 Settlement and Liquefaction Analyses

Settlement analyses and evaluation of liquefaction potential for the tailings were performed for the tailings cells. A discussion of the analyses and results are provided in Appendix F.

One-dimensional settlement analyses were conducted to evaluate settlement due to placement of final cover, dewatering of the tailings cells, long-term static (creep) settlement, and seismically induced (seismic) settlement. The results of these analyses of specific locations were used to evaluate differential settlement and the potential for cover cracking. The CPT locations in Cell 2 and 3 from the October 2013 tailings investigation (MWH, 2015a) were selected as the locations for the settlement analyses. Parameters used for the settlement analyses are summarized in Appendix F. Tailings profiles and properties are based on results presented in MWH (2015a). Parameters for cover materials are based on cover material testing conducted in 2010 and 2012 (summarized in Appendix A). Evaluation of total settlement due to final cover placement and dewatering indicates potential future settlement during active maintenance ranging from 0.9 to 1.6 feet.

The majority of this settlement is expected occur after Phase 1 cover construction with the remaining settlement occurring soon after Phase 2 cover construction. During this time, additional fill may be placed in low areas to maintain positive drainage of the cover surface. The estimated total predicted future long-term settlement that could occur (due to creep and seismic settlement) after the maintenance period is complete ranges from approximately 0.3 to 0.7 feet. Estimates of total long-term settlement were calculated by summing the static creep and seismic settlement estimates. As such, these estimates are considered somewhat conservative, as they are not independent (i.e. as long-term static creep progresses, void ratio reduction will occur and the potential for seismic settlement will reduce over time as a result). The estimated differential settlement after completion of active maintenance is sufficiently low that slope reversal and ponding is not expected to occur on a cover slope of 0.5 to 1.0 percent.

In addition, the results indicate that cracking of the highly-compacted radon barrier due to settlement-induced strains is not expected.

Liquefaction analyses were performed to evaluate the risk of earthquake-induced liquefaction of the tailings. Two methods (Idriss and Boulanger, 2008; Youd et al., 2001) were used for the analyses. Material properties were obtained from results of laboratory tests on tailings samples collected during the October 2013 tailings investigation of Cells 2 and 3 (MWH, 2015a). Other parameters used were based on CPT data measured during the October 2013 tailings investigation. Results of the site-specific PSHA (MWH, 2015b) were used in the analyses and include a PGA of 0.15g for an approximate 10,000-year return period, with the mean seismic source being a magnitude (Mw) 5.5 event occurring 20 km from the site. Computed factors of safety against liquefaction range from 2.0 to 2.8. Based on the calculated factors of safety, the tailings are not susceptible to earthquake-induced liquefaction.

4.9 Erosion Protection

The erosional stability of the reclaimed tailings cells was evaluated in terms of long-term water erosion under extreme storm conditions. The analyses were conducted in general accordance with NRC guidelines (NRC, 1990; Johnson, 2002). A description of the analyses performed is presented in Appendix G.

The components of erosion protection for the reclaimed tailings cells consist of the following:

- The cover on the top surface of Cells 1, 2, and 3, with slopes of 0.5 percent, would be constructed as a vegetated slope, with 6 inches of topsoil.
- The portions of Cell 2 with a top surface of 1 percent slope, and the portions of Cells 4A and 4B with 0.8 percent slope, would be constructed as a vegetated slope with 6 inches of topsoil mixed with 25 percent (by weight) gravel (maximum diameter of 1 inch).
- Erosion protection of external (5H:1V) side slopes would be provided by various sized angular and rounded riprap with layer thicknesses ranging from 6 to 8 inches and median particle sizes ranging from 1.7 to 5.3 inches. A 6-inch layer of filter material would be placed between the erosional protection layer and underlying soil layer in locations with riprap greater than 1.7 inches. A narrow zone of this filter will also be placed at the interface between the riprap on the external side slopes and the cover surface erosion protection layer.
- The toe of embankment slopes will have erosional protection and scour protection on the west and east sides of the cells provided by a rock apron measuring approximately 10 inches deep and 5 feet wide, with a median particle size of 3.4 inches. On the south side of cells 4A and 4B, and east side of Cell 4A, the rock apron would be approximately 3 feet in depth, 13 feet in width, and have a median particle size of 10.6 inches. On the north side slope of the Cell 1 disposal area, the rock apron would be approximately 3 feet deep, 11 feet wide, and have a median particle size of 9 inches.
- The Sedimentation Basin area will be graded to 0.1 percent slope and constructed as a vegetated slope with 6 inches of topsoil.
- The Diversion Channel will be excavated into bedrock.

4.10 Tailings Dewatering

Cells 2, 3, 4A, and 4B are constructed to allow tailings dewatering. Dewatering analyses have been conducted for these tailings management cells assuming the cells receive tailings to the maximum permitted tailings elevation. Dewatering analyses for Cells 2 and 3 were conducted by MWH and are presented in Appendix J of MWH (2010). Dewatering analyses for Cells 4A and 4B were conducted by Geosyntec (2007a, 2007b). The pertinent excerpts from MWH (2010), Geosyntec (2007a, 2007b), and DRC (2008) are included in Appendix H and summarized in the following sections.

Water levels in Cells 2 and 3 were measured during the October 2013 tailings investigation (MWH, 2015a). Results of the investigation indicated migration of water towards the sump in Cell 2. This was expected since water has been pumped from the Cell 2 sump since 2008. Dewatering of Cell 3 has not yet started and the October 2013 investigation reflected this, with measured water levels a few feet below the tailings surface.

To monitor changes in water levels due to dewatering prior to and after final cover placement, installation of standpipe piezometers was recommended across the cells prior to the first phase of final cover placement and extension of the piezometers during final cover placement. These piezometers will provide information on the rate and extent of dewatering of the tailings. The piezometers are primarily located adjacent to the settlement monuments to minimize damage to the piezometers during cover construction, while providing sufficient locations to evaluate the water levels. Water levels are recommended to be monitored at the same frequency and duration as the settlement monuments. Standpipe piezometers were installed across Cell 2 in June 2016 and locations are shown in Appendix L.

4.10.1 Tailings Cells 2 and 3

Dewatering of Cells 2 and 3 is performed via the drain network consisting of perforated PVC pipe located across the base of the cells. The pipes drain to an extraction sump on the southern side of each cell. Tailings pore water drains by gravity to the sump and (for Cell 2) is then pumped to Cell 1 for evaporation. Dewatering of Cell 3 has not started. The design for the drains is the same for both cells, and each drain system covers an approximate area of 400 by 600 feet in each cell. The drain pipes are covered by an envelope of sand over the drains, in contrast to a continuous layer of sand across the bottom of the tailing cells.

The analyses of dewatering of Cells 2 and 3 were performed with the computer code MODFLOW (McDonald and Harbaugh, 1988; Harbaugh et al., 2000) with the Department of Defense Groundwater Modeling System (GMS) pre- and post-processor. The slimes drains were simulated with the Drain package in MODFLOW, and values of hydraulic conductivity were based on measured values reported for uranium mill tailings at a similar facility (MWH, 2010). A complete description of the dewatering modeling conducted for tailings Cells 2 and 3 is provided in Appendix J of MWH (2010), and is attached as Appendix H.1.

4.10.2 Tailings Cells 4-A and 4-B

The drain network design in Cells 4A and 4B is the same for each cell, and is different from that constructed in Cells 2 and 3. The drain network in Cells 4A and 4B consists of a series of 12-inch wide HDPE strip drains wrapped in geotextile, and covered by sand bags. The drain spacing is 50 feet across the entirety of both cells. The HDPE drains are connected to a perforated 4-inch diameter PVC pipe bedded in drain aggregate and wrapped in geotextile. The PVC pipe gravity drains the tailings water to the sump for extraction.

A tailings cell dewatering model was not constructed for Cells 4A and 4B because analytical solutions presented by Geosyntec Consultants (2007a, 2007b) were deemed adequate given the uniform distribution of the drain system in those cells. Material properties for tailings in Cells 4A and 4B were estimated based on results of laboratory tests and assuming the tailings would be similar to the tailings in Cells 2 and 3. Cell 4B is currently used for evaporation and has not received tailings. These analyses assume Cell 4B will be used for tailings storage in the future. Dewatering of Cells 4A and 4B are estimated to be dewatered significantly faster than Cells 2 and 3 due to the more extensive drain network.

4.11 Material Quantities

Material volumes required for construction of the interim cover, final cover, and erosion protection are provided in Table 4-1. The quantities of materials available for construction of the cover are also provided in Table 4-1. A summary of the volumes of borrow stockpiles was provided in Table 2-1. Sufficient quantities are available from on-site sources for the topsoil and random fill materials. The bedding and gravel materials would be obtained from off-site commercial sources. Three commercial sources have been identified as potential sources for the bedding and gravel materials. The potential off-site sources were listed in Section 2.5. Sufficient quantities of material are available from the off-site sources identified.

Table 4-1. Reclamation Cover Material Quantity Summary

Material	Quantity Required for Reclamation (cy)	Quantity Available (Identified Sources) (cy)
Topsoil (for Erosion Protection Layer)	195,000	284,100 (on-site stockpiles)
Gravel (1-inch minus for Erosion Protection Layer)	24,000	Sufficient quantity available (off-site commercial source)
Random Fill (total for additional Layer 1 material, Layer 2, and Layer 3)	3,500,000	3,596,621 (on-site stockpiles)
Riprap (for 5H:1V side slopes and rock aprons)	38,000	Sufficient quantity available (off-site commercial source)
Riprap Bedding/Filter Layer	16,000[1]	Sufficient quantity available (off-site commercial source)

Note:
1. Based on 6-inch thick medium sand bedding/filter layer beneath riprap.

5.0 CELL 2 COVER CONSTRUCTION AND PERFORMANCE ASSESSMENT

5.1 Overview

On November 11, 2015, DWMRC recommended that EFRI develop a plan to begin reclamation of the tailings management cells. This plan would consist of placing the proposed cover system presented in White Mesa Reclamation Plan, Revision 5.1 on Cell 2 and demonstrating acceptable cover performance via a performance monitoring program.

Cell 2 final cover construction will take place before final cover construction on other cells at the White Mesa Mill. Cell 2 final cover construction will occur in two phases and includes a performance monitoring test section (Primary Test Section) containing a lysimeter constructed in the southeast portion of Cell 2 concurrently with the Phase 1 cover placement. A Supplemental Test Section will be constructed north of the tailings management cells relating to vegetative cover and erosion control. The plan for implementing final cover placement on Cell 2 and performance assessment and monitoring is presented in Appendix L.

5.2 Cover Placement and Revegetation

Layer 1 of the reclamation cover was placed in stages on Cell 2 as interim cover from 1991 through 2008. The remaining reclamation cover layers will be placed in two phases.

Phase 1 cover construction began in April 2016, and includes placement of: (1) additional interim cover to achieve Layer 1 design grades prior to placement of cover Layer 2 and (2) the entirety of Layer 2. Between the first and second phase of cover placement, additional cover material will be placed as needed in low areas to maintain positive drainage of the Phase 1 cover surface.

A cover performance monitoring test section, containing a lysimeter, was constructed in the southeast portion of Cell 2 in the fall of 2016 concurrently with the Phase 1 cover placement. The Supplemental Test Section is proposed to be constructed in the fall of 2017. Instrumentation for monitoring Cell 2 after Phase 1 cover placement will also include settlement monuments and piezometers.

Cell 2 Phase 2 cover placement will occur after the following milestones have been met:

- Test section performance monitoring is complete
- Phase 1 cover settlement criteria has been met
- DWMRC approval of performance of the Cell 2 cover test section

Additional discussion of performance monitoring and settlement criteria is presented in Appendix L.

Phase 2 cover construction will consist of placement of Layer 3 and placement of Layer 4, the erosion protection layer. The top surface of the final cover will be revegetated after Phase 2 cover construction is completed. As-built reports will be provided to DWMRC within 90 days after completion of each phase of cover construction.

5.3 Cover Performance Assessment

EFRI constructed a performance monitoring test section within the Cell 2 cover concurrently with the Phase 1 cover placement. The test section will be monitored to assess performance of the overall cover system for the tailings cells. A Supplemental Test Section will be constructed north of the tailings management cells relating to vegetative cover and erosion control. Appendix L contains discussion of the Cell 2 cover performance assessment plan.

The performance monitoring area is constructed as a large Alternative Cover Assessment Program (ACAP) drainage lysimeter to provide direct measurement of all components of the water balance, except evapotranspiration. In-situ soil water content and temperature measurements of the cover soils will be taken within the performance monitoring area, and a weather station installed adjacent to the performance monitoring area will be used to collect weather data.

Percolation rate and vegetation success are the performance parameters for the cover system. The performance monitoring requirements follow NUREG/CR-7028 (Benson et al., 2011) and incorporate site-specific recommendations from Dr. Craig H. Benson (personal communication). Data from secondary variables (i.e. meteorological conditions, all water balance quantities, soil water content, soil temperature, in-service soil and vegetation properties, etc.) related to the primary performance parameter will be used for interpretative purposes, as recommended in NUREG/CR-7028 (Benson et al., 2011). Although performance criteria are not suggested in NUREG/CR-7028 for these parameters and are not stipulated herein, monitoring of these parameters is recommended so that the percolation data can be interpreted mechanistically.

Current monitoring of radon emanation rates from the top surface of Cell 2 and settlement will continue during placement of the Cell 2 cover. Existing settlement monuments will be extended upward during cover construction. Standpipe piezometers were installed across Cell 2 during Phase 1 Cell 2 cover construction to monitor water levels within the tailings. After Phase 1 cover construction is complete, it is recommended that settlement monuments and piezometers be monitored weekly for the first month, biweekly for the second month, and monthly thereafter.

Settlement and dewatering data will be evaluated concurrently with the cover performance monitoring. The evaluation will determine if sufficient settlement has occurred to facilitate Phase 2 cover placement. Decreasing trends in settlement followed by maximum of 0.1 feet (30 mm) of cumulative settlement over 12 months (for at least 90 percent of the settlement monuments) will be considered acceptable to proceed with placement of the Phase 2 Cell 2 cover.

Monitoring of Cell 2 will also occur after Cell 2 Phase 2 cover construction is complete and will include radon emanation, settlement, and vegetation monitoring. Closure monitoring is discussed in Section 6.4.

A data quality report will be provided to the DWMRC quarterly and a comprehensive performance monitoring report will be submitted annually to the DWMRC during monitoring. The annual performance monitoring report will include quarterly data quality reports and will also summarize settlement and standpipe piezometer monitoring, and include the annual vegetation monitoring report.

6.0 ADDITIONAL PLANS AND MONITORING PROGRAMS

6.1 Settlement Monitoring

There are two objectives for monitoring settlement associated with the tailings cells: (1) assurance that the materials in the tailings cells have stabilized prior to construction of the final cover system, and (2) verification that the final cover surface is not experiencing significant settlement after final cover construction. Monitoring of interim cover surface will be conducted at the end of operations to measure rates and locations of settlement prior to construction of the final cover system. After construction of the final cover system, settlement monitoring will be conducted as part of post-closure performance monitoring. Additional discussion on settlement monitoring is presented in Appendix I.

6.2 Revegetation Plan

Revegetation of the tailing cells at the Mill site will be completed following construction of the cover system. The revegetation process will establish a grass-forb community consisting primarily of native, perennial grasses and forbs that are highly adapted to the climatic and edaphic conditions of the site. Revegetation methods will follow state-of-the-art techniques for soil amendments, seedbed preparation, seeding and mulching. In addition, quality assurance and quality control procedures will be followed to ensure that revegetation methods are implemented correctly and the results of the process meet expectations. A revegetation plan presenting seedbed preparation, soil amendments, species types, seeding rates, and quality assurance is presented in Appendix J.

6.3 Final Cover Verification

Following construction of the final reclamation cover, testing will be performed to verify that the cover meets the requirements of long-term radon-222 emanation (less than 20 pCi/m^2-s averaged over the entire area of the tailings cell). Verification testing will be performed in accordance with procedures described in 40 CFR Part 61, Appendix B, Method 115, or another method of verification approved by the DWMRC. Verification testing will be conducted for the entire reclaimed tailings area at once. Results of the verification testing will be reported within 90 days of the completion of all testing and analysis relevant to the verification.

Measurement, calculation of radon-222 emanation or flux, and reporting will be performed in accordance with procedures described in 40 CFR Part 61, Appendix B, Method 115. The documentation will include the results of all measurements, the calculations and/or analytical methods used to derive radon flux, and the procedure used to determine compliance. EFRI will maintain these records will be maintained on site or at an off-site storage facility until the time of site transfer to the DOE.

6.4 Closure and Post-Closure Monitoring

The performance monitoring and verification tasks for the reclaimed tailings cells are consistent with plans for overall site reclamation and review guidelines in NRC (2003). Key tasks outlined below will be performed from the time of site reclamation until property transfer to the DOE.

- **Settlement.** After construction of the final reclamation cover, settlement monitoring will be conducted as discussed in Appendix I as part of post-closure performance monitoring to verify that the final cover surface is not experiencing significant settlement. It is recommended that settlement monuments be monitored weekly for the first month after final cover construction, biweekly for the second month, and monthly thereafter for the first two years. Quarterly monitoring is recommended after two years. A minimum monitoring period of 5 years is recommended. Decreasing trends in settlement followed by maximum of 0.1 feet (30 mm) of cumulative settlement over 12 months (based on 90 percent of the settlement monuments) is recommended as acceptable for defining when the final cover surface is no longer experiencing significant settlement.

- **Vegetative Cover.** The Revegetation Plan discussed in Section 6.2 and Appendix J will be followed. The vegetation performance will be monitored annually for ten years after final cover construction or until revegetation goals have been achieved.
- **Erosional Stability.** The erosional stability of the cover surface will be monitored on a semi-annual basis, most likely at the same time as the vegetation monitoring. Elements of the erosional stability monitoring are degree of vegetation cover (in terms of surface coverage), identification of settled or ponded areas (such as on the top surface), and identification of rills, gullies, or other areas of runoff concentration. Areas that are identified as having erosional stability issues will be monitored to determine if corrective action is necessary. Corrective action would include fill placement with topsoil or erosion-resistant materials on the surface, such as a gravel-admixture. The erosional stability of the cover surface will be monitored by EFRI until that responsibility is changed with property transfer to the DOE.

Denver, Colorado 80265

Subject: Stockpile Evaluation
Tailings Cell 4A, White Mesa Mill
Blanding, Utah

Dear Mr. Roberts:

GeoSyntec Consultants (GeoSyntec) is pleased to provide this letter report to International Uranium (USA) Corporation (IUC) presenting the results of the GeoSyntec soil stockpile evaluation at the White Mesa Mill facility (site) in Blanding, Utah. This stockpile evaluation was performed in accordance with an authorized proposal dated 5 October 2005.

INTRODUCTION

The site is located at 6425 S. Highway 191, approximately 6 miles south of the City of Blanding, San Juan County, Utah (Figure 1). The 5,415-acre site is bordered on all sides by undeveloped land that is sparsely vegetated. The mill is utilized to process ores and alternate feed streams for the extraction and enrichment of uranium and other approved materials.

BACKGROUND

In addition to marketable product produced during the milling process, ore spoils (tailings) and highly acidic wastewaters are also generated as process by-products. The tailings and wastewater are stored on site within constructed surface cells that are lined with low-permeability soil (clay) and geosynthetic materials to mitigate potential impacts to underlying soils and groundwater. Cell 4A was a previously constructed surface impound at the south end of the site (Figure 2) and contained a compacted clay liner and a geosynthetic liner.

PURPOSE

A new geosynthetic lining system may be installed in future cell base liner systems. In addition to the potential need for clay material for the construction of future base liner systems, clay material will be needed for final cover system installation overlying closed cells. Although many soil stockpiles exist on site, the material in many of these stockpiles would not meet specific permeability requirements and are not considered available for use.

Based on discussions between IUC and GeoSyntec during a 29 September 2005 meeting at the site, it was understood that clay soil may be available in two on-site stockpiles. Clay liner materials are typically required to have an in-situ hydraulic conductivity of 1×10^{-7} cm/sec or less. In order to prepare design drawings, appropriately budget and plan for the future liner system construction, and evaluate final cover system soil materials, the two existing soil stockpiles with potentially-suitable clay soil were characterized to evaluate quality and consistency of the material. In addition, a third on-site stockpile was sampled and evaluated at the request of IUC.

FIELD INVESTIGATION

As part of this investigation, soil from three existing on site soil stockpiles was sampled. Before field work began, GeoSyntec reviewed and discussed documentation for previous sampling events performed by others on many of the soil stockpiles on site. In agreement with IUC, stockpiles C1, C2, and RF5 were identified as potential stockpiles of clay material and were the focus of the GeoSyntec field evaluation and sampling event (Figure 2). Prior to mobilizing to site, GeoSyntec field personnel prepared a project-specific health and safety plan (HASP) for the field work to be performed.

The field investigation was performed for the three stockpiles on 10 and 11 November 2005. Soil stockpile evaluation was assisted by an IUC employee operating a Caterpillar 426B backhoe on 10 November 2005 and a Caterpillar front-end loader on 11 November 2005. Stockpile evaluation included the visual evaluation of stockpile surface and excavated test-pits and the collection and transport of soil samples for off-site laboratory geotechnical testing. General observations made during the stockpile evaluation by GeoSyntec field personnel, including surficial conditions of the three stockpiles, were recorded on Daily Field Reports (Appendix A).

On 10 November 2005 nine test-pits were excavated in soil stockpile C1, and seven test pits were excavated in soil stockpile C2. One test pit in stockpile C2 and two test pits in stockpile RF5 were excavated on 11 November 2005. The approximate test pit locations are shown on Figures 3 through 5. Test pits were excavated to depths ranging from approximately 2 to 10 feet below ground surface (bgs) and from approximately 10 to 15 feet long. Test pits excavated with the backhoe were approximately 2 feet wide and those excavated with the loader were approximately 6 feet wide. General visual observations were made of the materials excavated for each test pit and the soils were logged in general accordance with the American Society for Testing and Materials (ASTM) soil classification system, as outlined in ASTM standard D2488. Logs of the test pits are presented in Appendix A.

Representative soil samples were obtained from the soil cuttings in 5-gallon buckets and shipped, via courier, to the off-site geotechnical laboratory for further testing and classification.

LABORATORY TESTING

Geotechnical laboratory testing was performed on selected soil samples to evaluate the suitability of the soil within the stockpiles for use as clay liner. Laboratory testing was performed by a GeoSyntec subcontractor, Excel Geotechnical Testing. The following laboratory tests were performed in general accordance with ASTM test methods on selected soil samples or on a composite of two or more like samples, as selected by the GeoSyntec project manager:

- Grain size analyses (ASTM D422)
- Atterberg Limits (ASTM D4318)
- Laboratory Compaction by Modified Effort (ASTM D1557)
- Permeability (ASTM D5084)

The laboratory test results are presented in Appendix B and summarized in Table 1.

CONCLUSIONS AND RECOMMENDATIONS

Based on observations made during the field investigation and review of the results of the laboratory testing performed for this evaluation, the soil within each of the three on-site stockpiles (C1, C2, and RF5) is suitable for construction of the clay liner or soil cover. The soil encountered within the test pits performed for the three stockpiles was generally consistent (e.g. the soils encountered in the test pits performed in stockpile C1 were generally consistent throughout stockpile C1). The samples tested from all three stockpiles, although different, are generally suitable for use as clay liner.

Based on the results of laboratory testing, the on-site stockpile soils, compacted to a minimum relative compaction of 90 percent using modified effort and a moisture content of at least 4 percent above optimum, should have a hydraulic conductivity of less than $1x10^{-7}$ cm/s when subjected to a consolidation pressure of 30 pounds per square inch (consistent with anticipated bottom liner system normal stresses).

GeoSyntec recommends that the soil to be used from the three sampled stockpiles (C1, C2, and RF5) as clay liner be compacted to a minimum relative compaction of 90 percent of the maximum laboratory dry density, as determined in accordance with ASTM D1557 – Laboratory Compaction using Modified Effort. Soil compacted for the clay liner should be compacted at least 4 percent wet of the optimum moisture content as determined in accordance with ASTM D1557.

Should you have questions or require additional information regarding this letter report, please contact us at (858) 674-6559.

Sincerely,

Chad Bird, E.I.T. 020454

DAILY FIELD REPORT

PROJECT: IUC WHITE MESA MILL
LOCATION: BLANDING, UTAH PROJECT NO.: SC0349 TASK NO.: 01-06
DESCRIPTION: CLAY STOCKPILE SAMPLING DATE: 10 day NOV month 05 year
CONTRACTOR: NA CLIENT: INTERNATIONAL URANIUM CORP. THURSDAY
WEATHER: MOSTLY SUNNY, H ~ 70°?, L ~ 45°?

0745: ARRIVE ON SITE. MEET KEN MATOSHI OF INTERNATIONAL URANIUM ~~(USA)~~ (USA) CORPORATION (IUC).

~0815 - MEET RICH BARTLETT OF IUC. VISIT C1-S1 SOIL STOCKPILE AREA. ~~(KE)~~ R. BARTLETT ARRANGES FOR BACKHOE AND OPERATOR FOR WRITER.

- THE C1-S1 STOCKPILE BOUNDS ARE MANIFEST. PILE IS COVERED WITH LOW VEGETATION (~2-3 FT TALL). THERE ARE MANY LENGTHS OF APPARENTLY USED PREVIOUSLY POLYETHYLENE PIPES OF VARYING DIAMETER ON PILE AND OTHER DEBRIS. AN ACCESS ROAD ASCENDS FROM WEST TO EAST ALONG NORTH SIDE OF STOCKPILE.

0900 - OPERATOR W/ BACKHOE ASSIGNED (WAYLAN). PROCEED BACK TO C1-S1 (FIGURE 1) (CB)

0915 - TEST PIT C1S1-A AS SHOWN ON ATTACHED FIGURE. SOIL SAMPLE STICKY WHEN WETTED. MAKES BALL. STICKS TO SIDE OF PE PIPE. (SEE TEST PIT LOGS.)

~0950 - TEST PIT C1S1-B (SEE FIGURE). SOIL BELOW ~1.5' DIFFICULT TO DIG. DRY SURFACE (TOP ~1.5') SOIL SLOUGHS INTO TEST PIT (T.P.). DEEP SOIL IS STIFFER, HARD TO EXCAVATE.

~1010 - T.P. C1S1-C (SEE FIGURE). SOIL COMES OUT ~~(W)~~ MAINLY IN ~6" CLODS OR LARGER. DIFFICULT TO EXCAVATE W/ DEPTH. SIDEWALLS ARE STIFF AND MODERATELY SMOOTH. OBTAIN 5-GAL BUCKET SAMPLE.

1050 - TP. C1S1-D (SEE FIGURE). NOT TOO DIFFICULT TO EXCAVATE.

(CB) ~~1100~~ - 1105 - WAYLON BREAKS FOR LUNCH.

~~1110~~ 1115 - CALL NADER RAD AT SOILS LAB AND DESCRIBE SOIL OBSERVATIONS. NADER REQUESTS ~1/2 - 3/4 FULL 5-GALLON BUCKET SOIL SAMPLE VOLUME FOR LABORATORY TESTING.

1135 - RETURN TO C1S1. FINISH LOGGING C1S1-D.

~~1140~~ 1150 - C1S1-E (SEE FIGURE). SEMI-MOIST RED CLAY. COMES UP IN ~4" TO 6" CLODS, EASILY CRUMBLED. OBTAIN OFF-SITE LAB SAMPLE.

GeoSyntec Consultants

DAILY FIELD REPORT

DATE: 10 day NOV month 05 year

~1210 - TP C1S1-F (SEE FIG). REDDISH BROWN ~~CLAY~~ SAND W/ FINES AND BROWN SAND W/ FINES. SMALL (~1" φ) CLODS. ROUGH SIDEWALLS THAT EASILY SLOUGH. ~~SAND ROUGH SIDEWALLS. CLAY SMOOTH.~~ (CB)

~1230 - TP C1S1-G (SEE FIG). REDDISH TAN SAND W/FINES (SHALLOW) AND TANNISH RED CLAY (~1.5'+). SAND - DRY; ROUGH SIDEWALLS. CLAY - WETTER; SMOOTH SIDEWALLS; HARD TO EXCAVATE. OBTAIN SAMPLE FOR OFF-SITE LAB TESTING.

~1250 - TP C1S1-H (SEE FIG). REDDISH BROWN CLAY. DRY SHALLOW; ROUGH SIDEWALLS. WETTER DEEPER; SMOOTH SIDEWALLS. SOME BROWN CLAY CLODS, EASILY CRUMBLED. DIFFICULT TO EXCAVATE DEEP. ~~X~~ (CB)

~1310 - TP C1S1-I (SEE FIG). REDDISH TAN CLAY SHALLOW. ROUGH SIDEWALLS. DRY.

1325 - EXCAVATOR IS LEAKING HYDRAULIC FLUID AND NEEDS REPAIR. TP C1S1-I EXCAVATION DISCONTINUED.

1350 - TP C1S1-I EXCAVATION RESUMES BEFORE REPAIR COMPLETE. REDDISH BROWN CLAY (~1.0' - ~2.0'). HARD CLODS: ~4"-6" φ. DIFFICULT EXCAVATION DEEPER. CONCLUDES C1S1 SAMPLING.

~1410 - ARRIVE AT C2S1 STOCKPILE. PILE IS DOTTED WITH A FEW SMALL BUSHES, BUT IS (CB) MOSTLY UNVEGETATED.

~~THE~~ (CB) 1415 - TP C2S1-A (SEE FIGURE 2). SOIL IS BROWN SAND W/SOME FINES AND FRAGMENTS OF SANDSTONE. SOIL IS EASILY EXCAVATED. SANDSTONE: COMBINATION OF EASY + DIFFICULT TO CRUMBLE.

- WITH END OF WORK DAY APPROACHING, THE WRITER REQUESTS HOE OPERATOR TO EXCAVATE SEVERAL TEST PITS IN ADVANCE OF LOGGING. ~~EXCA~~ (CB) WRITER DIRECTS LOCATIONS. TP C2S1- ~~B~~ (CB) B (CB) THROUGH F. EXCAVATED BEFORE END OF DAY. THIS PITS NOT LOGGED.

1530 - RETURN TO COMPLEX AREA. CHECK PERSONS FOR RADIOACTIVITY W/ GEIGER COUNTER. NONE DETECTED.

1545 - DEPART SITE.

0.25 HR OFF-SITE PHONE MEETING W/ GREG CORCORAN (GEOSYNTEC) REGARDING FIELD ACTIVITIES.

PROJECT: IUC WHITE MESA MILL

LOCATION: BLANDING, UTAH PROJECT NO.: SC0349 TASK NO.: 01-06

DESCRIPTION: CLAY STOCKPILE SAMPLING DATE: 11 day NOV month 05 year

CONTRACTOR: NA CLIENT: INTENATIONAL URANIUM (USA) CORPORATION (IUC) FRIDAY

WEATHER: OVERCAST, T-STORMS, H ~ 55°?, L ~ 35°?

0700 - ARRIVE ON SITE. MEET ~~HAROLD~~ CB RICH BARTLETT (IUC). DISCUSS OBTAINING SAMPLES FROM ~~CL~~ CB SOIL STOCKPILE RFS-S1 FOR OFF-SITE LAB TESTING. PER PHONE CONVERSATION W/ GREG CORCORAN (GEOSYNTEC) ON 10 NOV 05, THIS HAS BEEN AGREED TO AND DIRECTED BY HAROLD ROBERTS OF IUC.

0710 - MEET WAYLON (EQUIPMENT OPERATOR). CAT 426 B HOE UTILIZED YESTERDAY IS BEING USED FOR OTHER PLANT ACTIVITIES. A LOADER WILL ALTERNATELY BE USED. (REMAINING EXCAVATIONS ARE INTO STOCKPILE SIDESLOPES.) CB (SEE FIGURE 2)

0715 - ARRIVE AT C2S1 STOCKPILE. BEGIN LOGGING TEST PITS.

0720 - ~~C2S1~~ CB TP C2S1-B - EASILY EXCAVATED (ON 10 NOV 05). MAINLY BROWN SAND W/ SOME CLAY ~~+ SAND~~ CB CLODS (EASILY BROKEN).

~0735 - TP C2S1-C - EASILY EXCAVATED (ON 10 NOV 05). MOSTLY SAND W/ FINES, BUT POSSIBLY CLAY AT BOTTOM - MAY BE COMPACTED, WETTER SAND. CONTAINS SOFT AND HARD PIECES OF SANDSTONE. OBTAIN SAMPLE FOR OFF-SITE LAB TESTING.

~0750 - TP C2S1-D - EASILY EXCAVATED (ON 10 NOV 05). DUG INTO SIDESLOPE OF PILE. MAINLY BROWN TAN SAND. CONTAINS SANDSTONE/CLAYSTONE PARTICLES - EASY AND DIFFICULT TO CRUMBLE.

~0805 - TP C2S1-E - TANNISH BROWN SAND. NOTABLY VERY ROUGH SIDEWALLS. COMES OUT MAINLY IN LARGE HARD PIECES OF SANDSTONE.

~0820 - TP C2S1-F - TANNISH BROWN SAND W/FINES AND SANDSTONE PIECES. SOME SANDSTONE PIECES ARE GRAY. OBTAIN SAMPLE FOR OFF-SITE LABORATORY TESTING.

~0840 - TP C2S1-G - EXCAVATED TODAY W/ LOADER INTO SIDESLOPE OF STOCKPILE. COMPARATIVELY FEWER FINES AND SANDSTONE. OBTAIN SAMPLE FOR OFF-SITE LAB TESTING. RAIN AND T-STORMS IN AREA: EVACUATE.

(SEE FIGURE 2 FOR C2S1 TEST PIT LOCATIONS)

Dear Mr. Sealy:

We have completed the tests ordered on the four samples shipped to us. The results are as follows:

Sample	Radium pCi/gm	Emanation Fraction	Diffusion Coeffic.	(g/cm^3) Density	Moisture	Saturation
Tailings	981±4	0.19±0.01	2.0E-02	1.45	13.2	0.39
			8.4E-03	1.44	19.1	0.56
Composite (2,3,&5)			1.6E-02	1.85	6.5	0.40
			4.5E-04	1.84	12.5	0.75
Site #1			1.6E-02	1.85	8.1	0.48
			1.4E-03	1.84	12.6	0.76
Site #4			1.1E-02	1.65	15.4	0.63
			4.2E-04	1.65	19.3	0.80

The samples will be shipped back to you in the next few weeks. If you have any questions regarding the results on the samples please feel free to call.

Sincerely,

Renee Y. Bowser

Dear Mr. Sealy:

The tests for radium content and radon emanation coefficient in the following samples have been completed and the results are as follows:

Sample	Radium (pCi/g)	Radon Emanation Coefficient
Random (2,3 & 5)	1.9 ± 0.1	0.19 ± 0.04
Site 1	2.2 ± 0.1	0.20 ± 0.03
Site 4	2.0 ± 0.1	0.11 ± 0.04

If you have any questions regarding these results please feel free to call Dr. Kirk Nielson or me.

Sincerely,

Renee Y. Bowser
Lab Supervisor

APPENDIX A.1.6

WESTERN COLORADO TESTING, INC.

1999a

The onsite random fill and clay stockpiles were sampled in characterized in a program detailed in the April 15, 1999, submittal to the NRC, "Additional Clarifications to the White Mesa Mill Reclamation Plan". A copy of this sampling and testing program are included in this Attachment as well as the results of the characterization work. The samples wee characterized for:

-- Classification
  - Grain size and sieve
  - Atterberg limits

-- Standard Proctor

The results of these tests for the onsite stockpiled material are included in this Attachment.

Soil Sampling and Testing Program – White Mesa Mill

The purpose of this Soil Sampling and Testing Program is to verify the soil classification, gradation and compaction characteristics (standard proctor) of the stockpiled random fill and clay materials that will be used for cover materials on the tailings cells at the White Mesa Mill. Additionally this program will verify the compaction characteristics and gradation of the random fill materials utilized in the platform fill previously placed on Cells 2 and 3.

Sampling

Sampling will take place on each of six stockpiles of random fill (designated RF-1 through RF-6 on Exhibit A), two clay material stockpiles (C-1 and C-2 on Exhibit A), and on platform fill areas in Cells 2 & 3. A total of 9 samples will be taken from the random fill stockpiles. Two (2) samples will be taken from the clay stockpiles and three (3) samples will be taken from the covered areas of the cells. Samples will be taken from test pits excavated by a backhoe. Samples will be taken from a depth of 8 feet in stockpiles and from 2 foot depth in cells. One backhoe bucket full of material will be taken from the test pit at the specified depth and dumped separately. This sample will be quartered and one quarter will be screened to minus 2" (rocks over 8" will be removed prior to screening). Two five gallon sample buckets will be filled with sample randomly selected from the screened fraction. Oversized material remaining after the screening of the sample will be visually classified and then weighed. Sample locations will be indicated on a site map and sample descriptions will recorded and maintained in the facility's records. A total of fourteen samples will be submitted for testing during this program.

Testing

Samples will be packaged and shipped to a certified commercial testing laboratory for testing. Tests will be run on each sample for standard proctor (ASTM D698), particle size analysis (ASTM C117 and ASTM C136), soil classification (ASTM D2487) and plasticity index (Atterberg limits ASTM D4318).

Subject: Soil Sample Testing

As requested, we have completed the soil laboratory work for International Uranium USA Corporation. The testing performed included the following:

- 21 Sieve Analyses
- 21 Atterberg Limit Tests
- 21 Standard Proctor Tests (ASTM D698)
- 6 Hydrometer Tests
- 6 Specific Gravity Tests

Data sheets are included for each test except for the specific gravities. The results of these are shown below:

Sample	Avg. Bulk Specific Gravity	Avg. Bulk Specific Gravity (SSD)	Apparent Specific Gravity	Absorption Percent
C2 - TS1	2.337	2.468	2.673	5.372
C2 - TS2	2.137	2.392	2.868	11.926
C2 - TS3	2.157	2.359	2.705	9.396
C2 - TS4	2.265	2.432	2.721	7.402
C3 - TS1	2.456	2.562	2.746	4.294
C3 - TS2	2.349	2.464	2.655	4.900

We have been happy to be of service. If you have any questions or we may be of further assistance, please call.

Respectfully Submitted:

14.0

Notes:

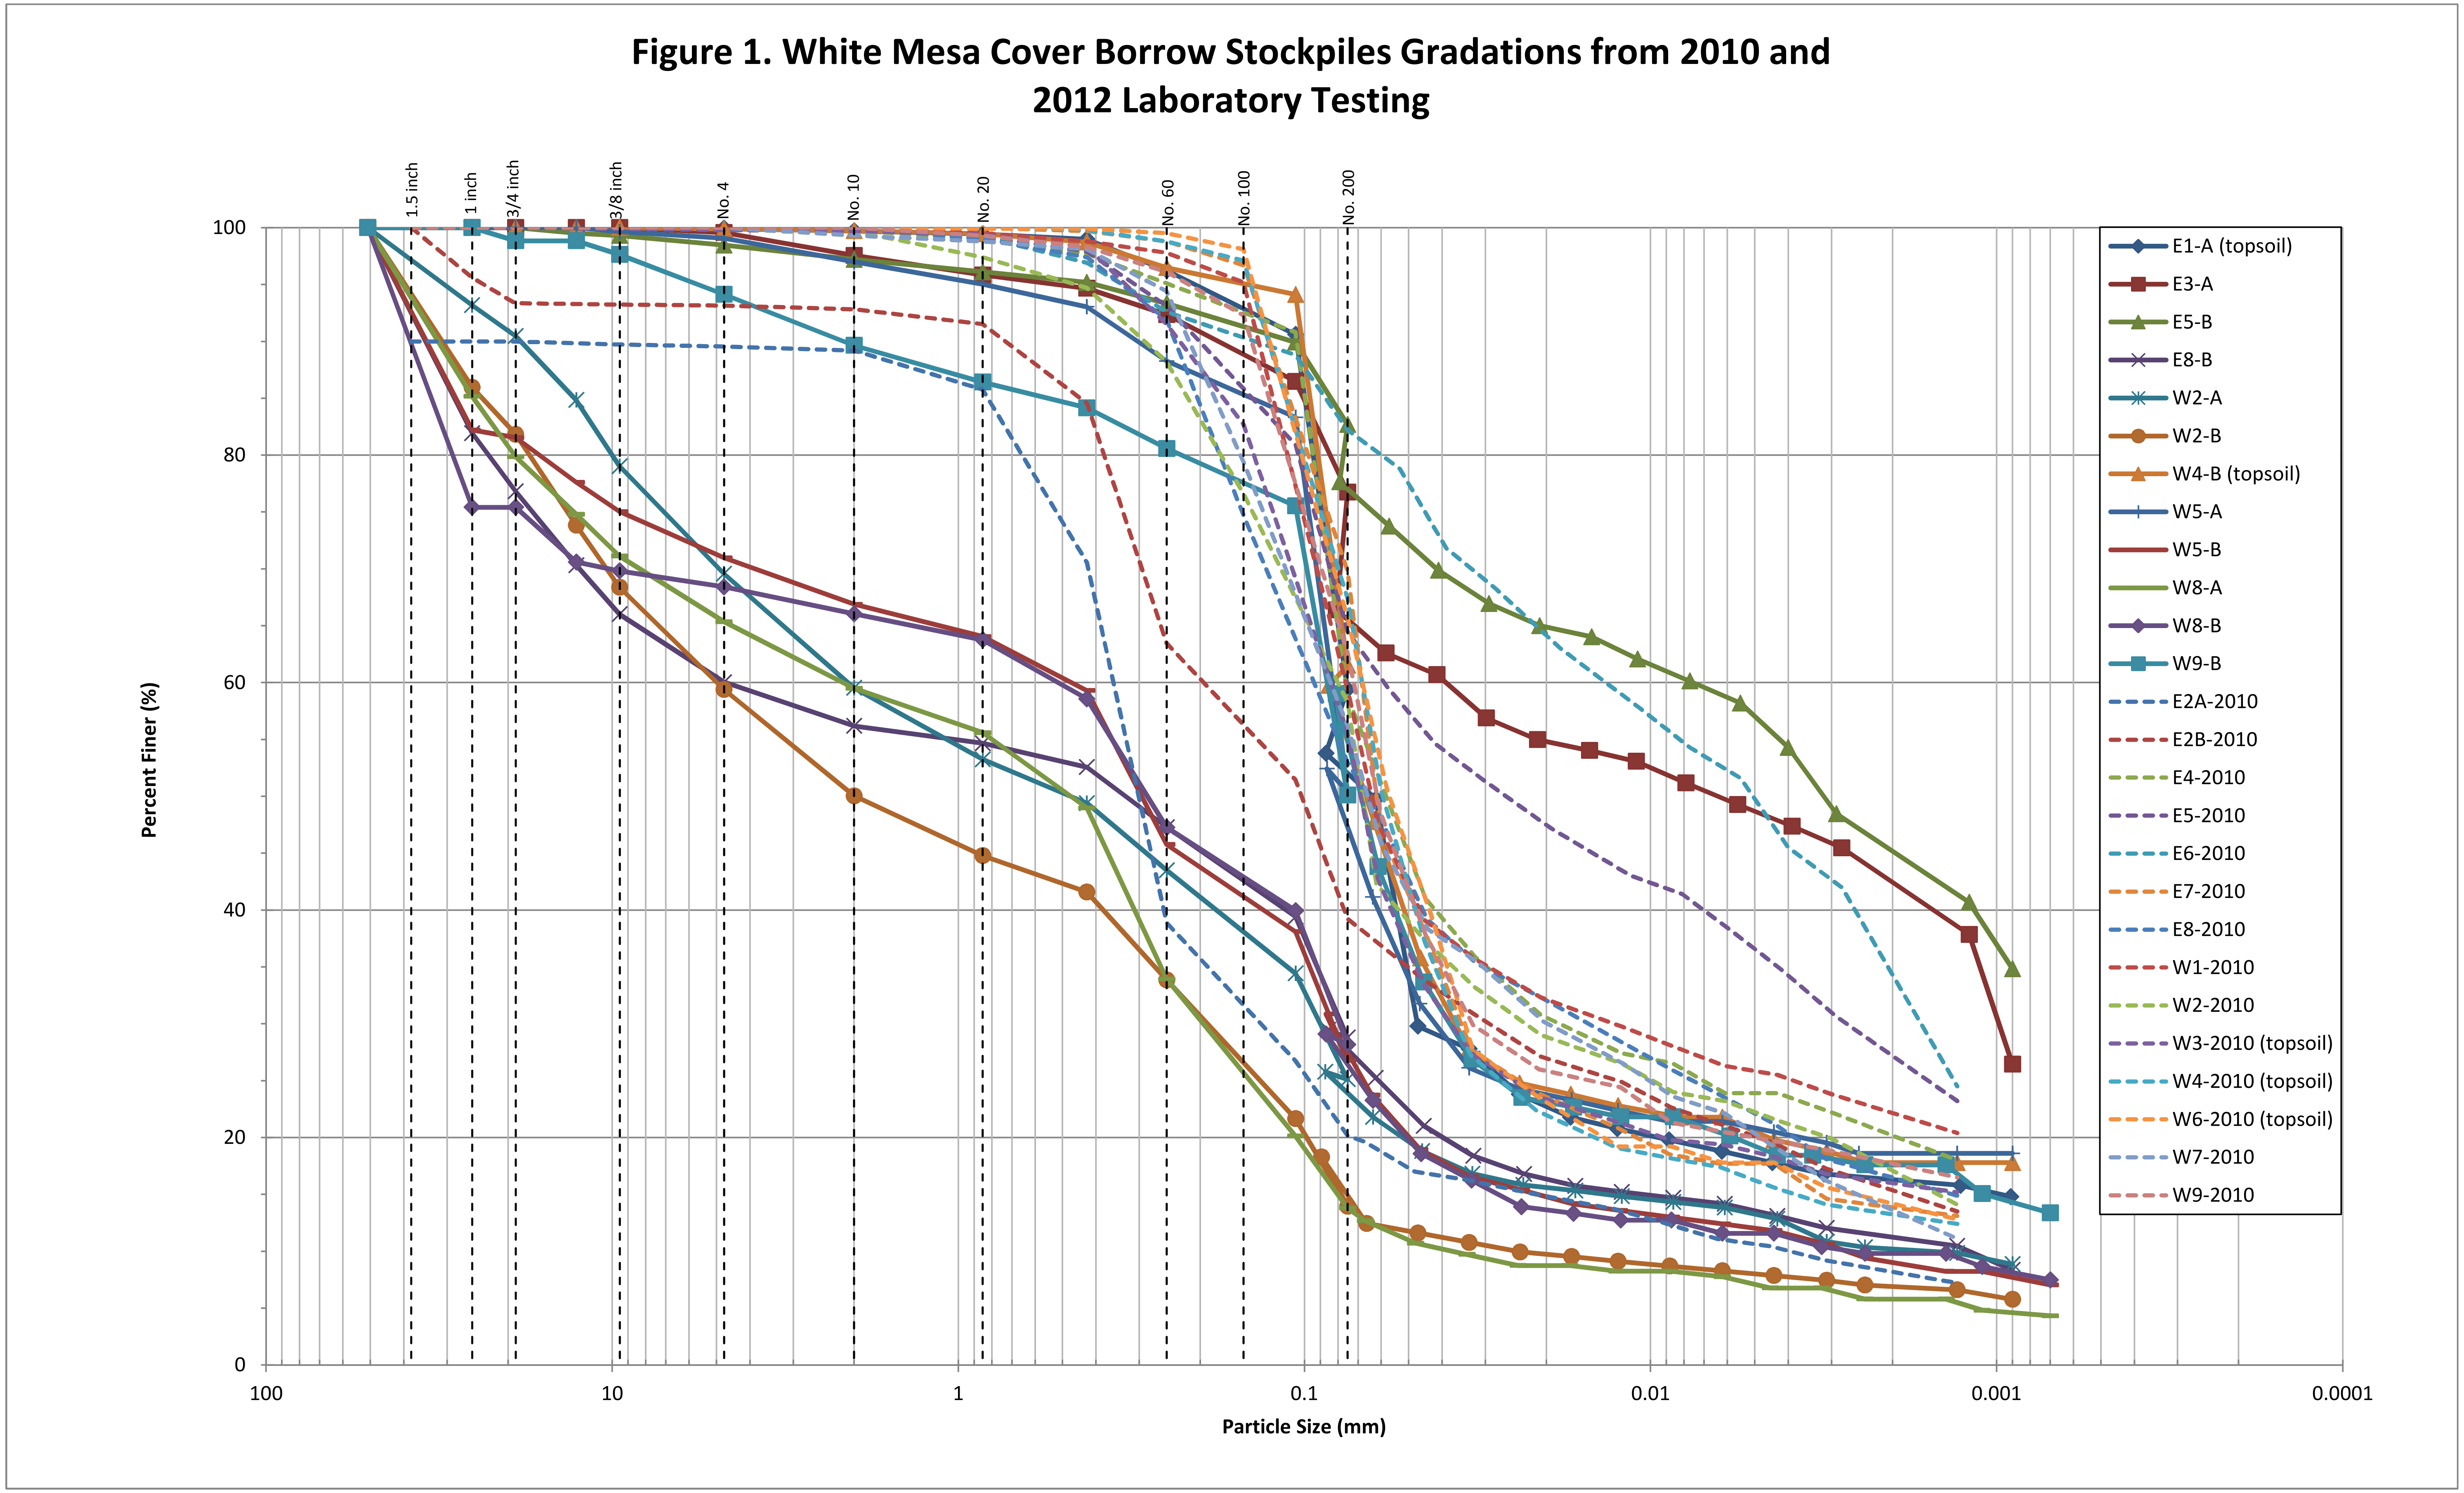
1. Volumes estimated using 2009 topography and assuming a relatively flat bottom surface, except for stockpiles W5, W8 and W9. The volumes for stockpiles W8 and W9 were estimated by comparing the 2011 versus 2009 topography.
The volume for stockpile W5 was estimated using a combination of both methods.

2. LL = Liquid Limt, PL = Plastic Limit, PI = Plasticity Index (PI = LL-PL)

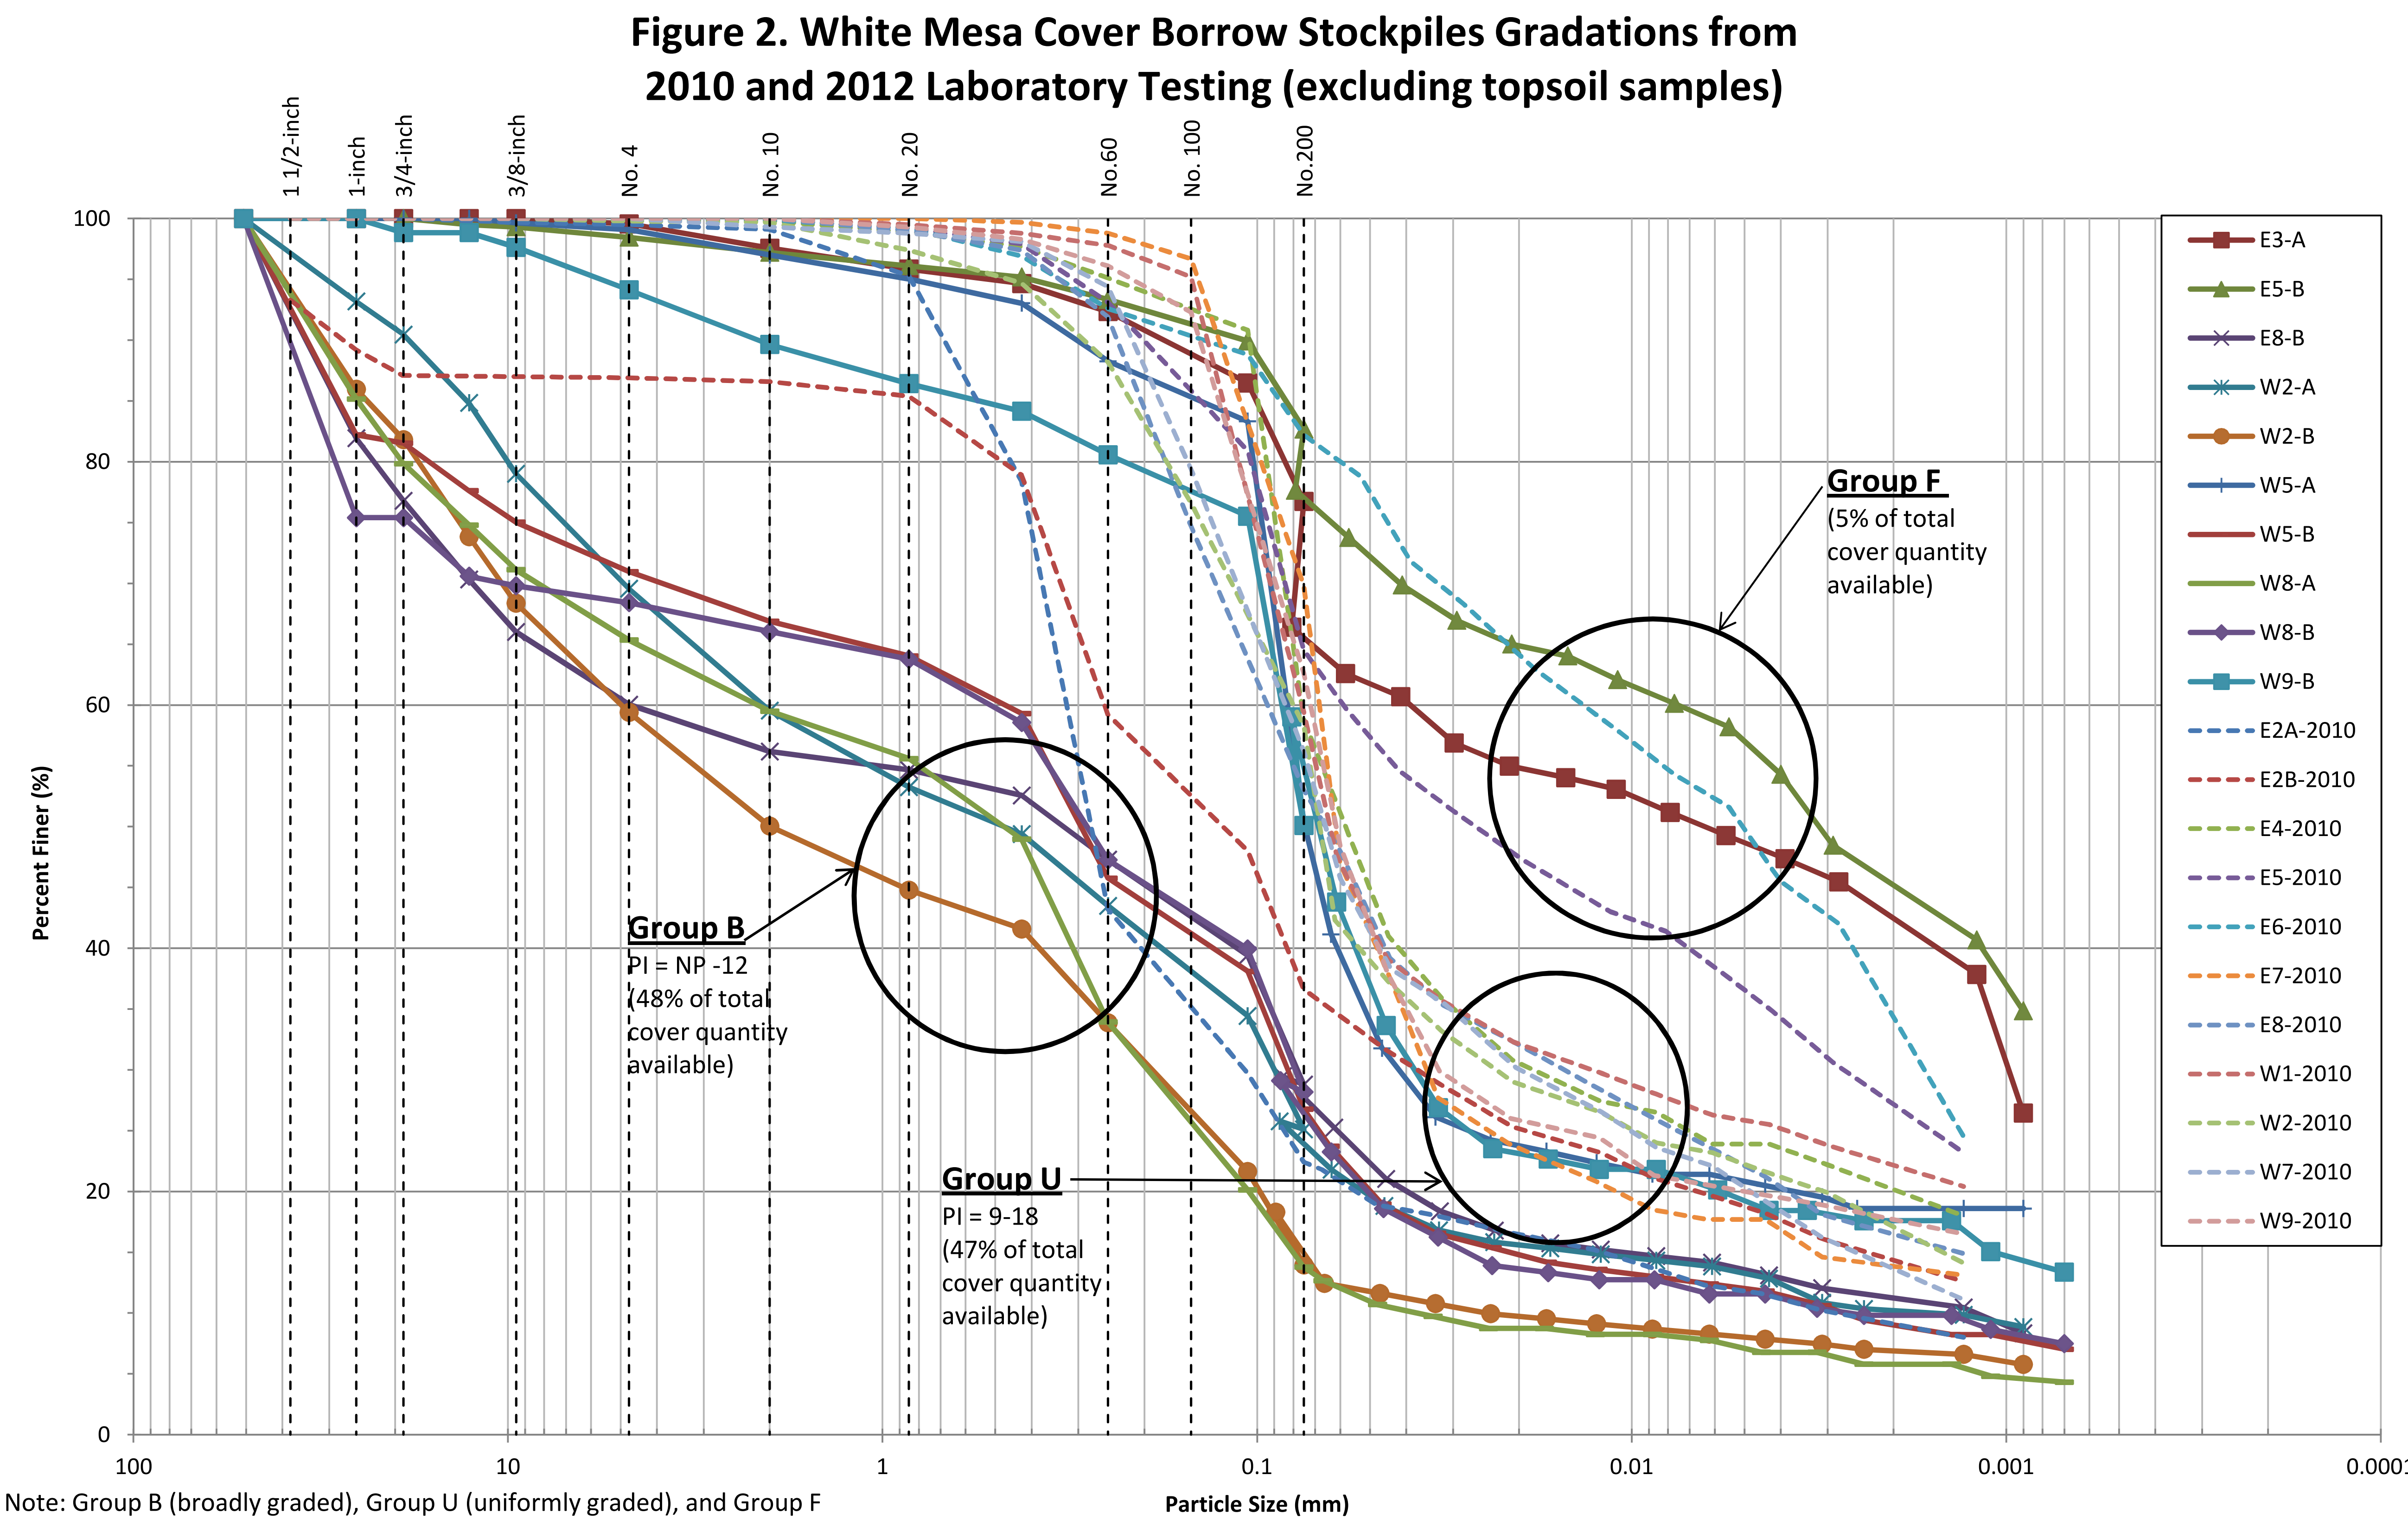
3. Gravel = 4.75 mm to 75 mm, Sand = 0.075 mm to 4.75 mm, Fines: Silt = 0 .075 mm to 0.002 mm, Clay = less than 0.002 mm

4. Group B (broadly graded), Group U (uniformly graded), and Group F (fine textured) based on evaluation of gradations and Benson (2012)*.

*Benson, C., 2012. Electronic communication from Craig Benson, University of Wisconsin-Madison, to Melanie Davis, MWH Americas, Inc., regarding evaluation of gradations performed for potential cover soils for White Mesa, May 20.



2010 and 2012 Cover Soil Gradations_mmd.xlsx



Note: Group B (broadly graded), Group U (uniformly graded), and Group F (fine textured) based on evaluation of gradations and Benson (2012)*.

*Benson, C., 2012. Electronic communication from Craig Benson, University of Wisconsin-Madison, to Melanie Davis, MWH Americas, Inc., regarding evaluation of gradations performed for potential cover soils for White Mesa, May 20.

INDEX PROPERTIES OF SOILS FROM BLANDING, UTAH

Geotechnics Report No. 12-37

Wisconsin Geotechnics Laboratory

University of Wisconsin-Madison
Madison, Wisconsin 53706
USA

20 May 2012

1. SCOPE

This report describes results of laboratory tests conducted to determine the specific gravity of solids, Atterberg Limits, and particle size distribution of twelve (12) soil samples from Blanding, Utah. The soils were delivered to the Wisconsin Geotechnics Laboratory as disturbed samples in 20-L buckets (2 buckets per soil).

2. METHODS

The two buckets of soil for each sample were inspected, thoroughly blended by hand, and then tested to determine the specific gravity of solids, Atterberg Limits, and particle size distribution. The following ASTM methods were employed on the blended samples:

D 422 Standard Test Method for Particle-Size Analysis of Soils

D 854 Standard Test Methods for Specific Gravity of Soil Solids by Water Pycnometer

D 4318 Standard Test Methods for Liquid Limit, Plastic Limit, and Plasticity Index of Soils

3. RESULTS

A summary of the index properties is provided in Table 1. The particle size distribution curves are summarized in Fig. 1. Data recorded from the tests are in the appendix.

Table 1. Summary of index properties for soils from Blanding, Utah.

COMPACTION AND HYDRAULIC PROPERTIES OF SOILS FROM BLANDING, UTAH

by

C.H. Benson and X. Wang

Geotechnics Report No. 12-41

Wisconsin Geotechnics Laboratory

University of Wisconsin-Madison
Madison, Wisconsin 53706
USA

24 July 2012

1. SCOPE

This report describes results of laboratory tests to determine the compaction and hydraulic properties of soil samples from Blanding, Utah. The soils were delivered to the Wisconsin Geotechnics Laboratory as disturbed samples in 20-L buckets (2 buckets per soil). Index properties of the soils were determined previously and are reported in Geotechnics Report No. 12-37.

2. METHODS

The same soil samples used for index properties testing were used for the tests conducted in this study. Tests were conducted to determine standard Proctor compaction curves, saturated hydraulic conductivity, soil water characteristic curves (SWCCs), and 1.5 MPa moisture content. The following ASTM methods were employed:

D 698 Standard Test Methods for Laboratory Compaction Characteristics of Soil Using Standard Effort (12 400 ft-lbf/ft (600 kN-m/m))

D 5084 Standard Test Methods for Measurement of Hydraulic Conductivity of Saturated Porous Materials Using a Flexible Wall Permeameter

D 6836 Standard Test Methods for Determination of the Soil Water Characteristic Curve for Desorption Using Hanging Column, Pressure Extractor, Chilled Mirror Hygrometer, or Centrifuge

Test specimens for the saturated hydraulic conductivity, SWCC, and 1.5 MPa moisture content tests were prepared at 85% of maximum dry unit weight and optimum water content per standard Proctor, as specified by the requestor.

Saturated hydraulic conductivity of each test specimen was measured in a flexible-wall permeameter following the methods in ASTM D 5084. The backpressure was set at 30 psi and the hydraulic gradient was 10. The effective stress was set at 5.0 psi to simulate the low state of stress in a cover while ensuring good contact between the membrane and the test specimen.

The wet end of the SWCC was measured following the procedures in ASTM D 6836 using a hanging column (Method A) or a pressure plate extractor (Method B). A chilled mirror hygrometer (Method D) was used to complete the dry end of the SWCC after the hanging column test or pressure plate test was complete. SWCCs were prepared by combining data from the pressure plate and chilled mirror hygrometer tests as described in D 6836. van Genuchten's equation was fit to the SWCC data:

$$\frac{\theta-\theta_r}{\theta_s-\theta_r}=\left[\frac{1}{1+(\alpha\psi)^n}\right]^m \qquad (1)$$

where θ is volumetric water content, θ_r is residual water content, θ_s is saturated volumetric water content, ψ is matric suction, and α, m, and n are fitting parameters. Equation 1 was fit to the data using a non-linear least-squares optimization procedure with the constraint $m = 1-n^{-1}$.

Moisture contents at 1.5 MPa were determined using the procedures in Method D of ASTM D 6836. Test specimens were prepared at three moisture contents bracketing a suction of 1.5 MPa. Moisture content was then regressed on suction, and the moisture content at 1.5 MPa was determined from the regression equation.

3. RESULTS

Optimum water contents and maximum dry unit weights from the compaction tests are summarized in Table 1. Saturated hydraulic conductivities and van Genuchten parameters for the SWCCs are summarized in Table 2. Gravimetric moisture contents at 1.5 MPa are summarized in Table 3. Data recorded from the tests are in the appendix.

Table 1. Summary of index properties for soils from Blanding, Utah.

FREEZE/THAW MODELING

White Mesa Uranium Mill
Frost Penetration Analysis

May 21, 2012

Geo-Smith Engineering, LLC
2591 Legacy Way
Grand Junction, CO 81503

Problem Statement:

Depth of frost penetration into the final cover for the proposed White Mesa uranium mill tailings impoundment will be determined using the procedure adopted by the U.S. Department of Energy and accepted Nuclear Regulatory Commission (DOE, 1989). The depth of freezing into a soil cover (depth of frost penetration) is governed by the local climate, soil material and soil moisture content expected during the operational life of the cover. A computational procedure to predict frost depth was initially proposed by Berggren (1943), later improved and codified by Aldrich and Paynter (1953). Smith and Rager (2002) apply these previous studies to determine an adequate thickness of a protective soil layer to protect an underlying compacted soil.

Method of Solution:

- Obtain site-specific climate data for the site from historic records kept by the Western Regional Climate Center at the Desert Research Institute (DRI).
- Use the method described in Smith and Rager (2002) to predict the maximum depth of frost penetration into a design soil cover profile at a specific site, based on the site's maximum and minimum temperatures. Temperatures are analyzed for a "Frost Year", a year beginning October 1st running through September 30th. This depth will determine the thickness of protective soil required to overlie a compacted soil radon/infiltration barrier.

Sources of Formula and References:

Modified Berggren Formula (MBF), (1968). U.S. Army Cold Regions Research and Engineering Laboratory, CRREL Special Report SR 122, Oct.

Data:

- Daily maximum-minimum temperature data are available for Blanding, UT from the Western Regional Climate Center back to the 1920's. Some years contain insufficient data to use the procedure proposed by Smith and Rager (2002), however an acceptable range of data exists.

- Spreadsheet data reduction used and presented in Attachment B.1.

- Final cover configuration for the upper portion of the cover section for the White Mesa mill tailings is presented in Table A.

Table A
Cover Material Soil Properties for Freeze/Thaw Analysis

Cover Layer	Design Thickness (inches)	Placed Density (pcf)	Gravimetric Water Content (%)
Erosion Protection (topsoil to rock mulch with 75% topsoil/25% minus 1-inch gravel)	6	99 to 107	6
Water Storage/Biointrusion/Frost Protection/Radon Attenuation Layer (low compaction water storage, rooting zone)	-	99	7.8

Calculation Procedure:

- *Step 1 Determine Freeze-Index Parameters*
  Climate data consisting of 53 years of at least 95% maximum and minimum daily air temperatures are available for the Blanding, UT NWS station. The procedure outlined in Smith and Rager (2002) was followed to compute the air-freeze index (degree-days), duration of freeze, and mean annual temperature for each station and year. Spreadsheets used in data reduction are provided in Attachment B.1 while plotted data are included as Attachment B.3.

- *Step 2 Determine Surface Temperature Correction Data*
  The daily temperature data used to determine the freeze-index parameters are typically measured 1.5 m above the ground surface. However, measured ground temperatures can be greater than air temperatures due to the effects of snow cover, net solar radiation, thermal conduction from warmer soils below the surface, and convective heat transfer (Smith and Rager, 2002). The ratio of the surface-freeze index to the air-freeze index is related through a factor, N. Because of the complexity and uncertainty between the freeze indices, an estimate for N recommended for practitioners (Army and Air Force, 1988) and Smith and Rager (2002) is 0.7.

- *Step 3 Determine Soil Thermal Properties*
  Soil thermal properties: thermal conductivity, heat capacity, and latent heat of fusion are products of empirical relationships between the dry unit weight (pcf) and gravimetric moisture content (%). These relationships are reproduced in Aitken and Berg (1968) originally published by Aldrich and Paynter (1953) and Kersten (1949). Thermal properties vary between fine-grained and coarse-grained soil types with fine-grained soils providing greater insulating properties.

- *Step 4 Determine Annual Frost Depths*
  Annual frost depths were determined for each of the subject years using the Modified Berggren Formula (MBF) as discussed in Smith and Rager (2002). The MBF was converted to PC software by the U. S. Army Corps of Engineers in 1968. Computer output for each year analyzed, including design air freezing index, design surface freezing index, mean annual temperature, length of freezing season, and total frost penetration, are presented as Attachment B.2.

- *Step 5 Determine Extreme Frost Depth*
  Extreme-value frost depths for the 200-year recurrence interval are determined by extrapolating beyond the record of observed data using the cumulative probability distribution of the Gumbel function (Smith and Rager, 2002). Frost depths are plotted in relation to the standard variate and recurrence interval, and linear regression is used to extrapolate and interpolate freezing depths. Graphical results of the extreme frost depth analysis are included in Attachment B.3, illustrating a maximum frost penetration of 32 inches for a recurrence interval of 200 years (0.5% chance of occurrence in any given year) with surface factor of 0.7.

Discussion:

The depth of frost penetration is reduced when the soil-water content increases because frozen water insulates underlying soils, thus the drier the soil the greater the depth of frost penetration. Also, given similar density and moisture conditions, the depth of frost penetration into coarse-grain soils, such as a rocky soil layer, is slightly greater than for a fine-grained soil layer due to lower thermal capacity of coarse-grain soils.
