APPENDIX C

RADON EMANATION MODELING

C.1 BACKGROUND

This appendix presents the results of modeling the emanation of radon-222 from the top surface of the proposed cover over the White Mesa tailing impoundments to achieve the State of Utah's long-term radon emanation standard for uranium mill tailings (Utah Administrative Code, Rule 313-24). These results comprise an update of radon emanation modeling presented in Attachment F of the 2009 Reclamation Plan (Denison, 2009) and Appendix H of the Infiltration and Contaminant Transport Modeling Report (Denison, 2010), as well as an update to Appendix C of the 2011 Updated Tailings Cover Design report (MWH, 2011). This appendix provides a summary of additional analyses of radon attenuation through the proposed evapotranspiration (ET) cover, and incorporates the revised cover grading design, results of cover material testing conducted in 2010 and 2012 (summarized in Attachment B of EFRI, 2012), and results of tailings testing conducted in 2013 (presented in MWH, 2015).

The monolithic ET cover system evaluated in this appendix consists of the following layers from top to bottom:

- 0.5 ft (15 cm) Erosion Protection Layer (gravel-admixture or topsoil)
- 3.5 ft (107 cm) Water Storage/Biointrusion/Frost Protection/Radon Attenuation Layer (loam to sandy clay)
- 3.0 to 4.0 ft (91 to 122 cm) Radon Attenuation Layer (highly compacted loam to sandy clay)
- 2.5 ft (76 cm) Radon Attenuation and Grading Layer (loam to sandy clay)

The loam to sandy clay soil used to construct the ET cover, referred to in previous reports (Titan 1996, Knight Piesold 1999) as random/platform fill, is stockpiled at the site.

C.2 DESCRIPTION OF MODEL AND INPUT VALUES

The thickness of the reclamation cover necessary to limit radon emanation from the disposal areas was analyzed using the NRC RADON model (NRC, 1989). The model utilizes the one-dimensional radon diffusion equation, which uses the physical and radiological characteristics of the tailings and overlying materials to calculate the rate of radon emanation from the tailings through the cover. The model was used to calculate the cover thickness required to limit the radon emanation rate through the top of the cover to 20 picocuries per square meter per second (pCi/m^2-s), following the guidance presented in U.S. Nuclear Regulatory Commission (NRC) publications NUREG/CR-3533 and Regulatory Guide 3.64 (NRC 1984, 1989). The rate of emanation standard is applied to the average emanation over the entire surface of the disposal area.

The input parameters used in the model are based on engineering experience with similar projects, recent laboratory testing results for samples of random fill (summarized in Attachment B of EFRI, 2012) and tailings (MWH, 2015), in addition to available data from previous work by others, including Chen and Associates (1978, 1979, 1987), Rogers and Associates Engineering Corporation (1988), Western Colorado Testing (1999a, 1999b), IUC (2000), and Titan (1996). The available data from testing performed by others was summarized in Appendix A of the Updated Tailings Cover Design report (MWH, 2011). Appendix A will be revised for the next version of the Updated Tailings Cover Design report to include data from recent random fill and tailings testing. The input parameters and values used in the model are outlined below.

C.2.1 Thickness of Tailings

The thickness of tailings currently deposited in Cells 2 and 3 is approximately 30 ft (914 cm), while the anticipated tailings thickness deposited in Cells 4A and 4B will be approximately 42 ft (1,280 cm). As documented in NRC Regulatory Guide 3.64, a tailings thickness greater than 100 to 200 cm is effectively equivalent to an infinitely thick radon source. Therefore, a thickness of 500 cm may be used in RADON to represent an equivalent infinitely thick tailings source of radon.

C.2.2 Radium Activity Concentration

The radium-226 activity concentration values for the tailings in the impoundments are estimated based on material inventory data provided by Energy Fuels Resources (USA), Inc. (EFRI). A summary of the material inventories for Cells 2 and 3 and the projected inventory for Cells 4A and 4B is provided in Attachment C.1. The radium-226 and thorium-230 activity concentrations are listed for each material in the inventories. These values were used to calculate a weighted average for radium-226 and thorium-230 activity concentrations for the tailings using the volume of material placed in Cells 2 and 3. In addition, these values were used to project radium-226 and thorium-230 activity concentrations for the materials to be placed in Cells 4A and 4B. Calculations for radium-226 from decay of thorium-230 were also made. These calculations are also provided in Attachment C.1. The results for Cell 3 and Cells 4A and 4B indicate the highest radium-226 values are a result of original radium-226 and radium-226 from thorium-230 decay at approximately 1000 years. The results are summarized below and in Table C.1.

Table C.1. Radium Activity Concentrations

Tailings Cell	Weighted Average Radium-226 Activity Concentration (pCi/g)	Weighted Average Thorium-230 Activity Concentration (pCi/g)	Total Radium-226 Activity Concentration (original radium-226 and radium-226 from thorium-230 decay) (pCi/g)
Cell 2	923	923	923
Cell 3	606	1048	758
Cells 4A and 4B	617	695	642

Random Fill and Erosion Protection. The radium activity of the random fill and erosion protection layer is assumed to be zero, based on guidance in Regulatory Guide 3.64 (NRC, 1989) which states that radium activity in the cover soils may be neglected for cover design purposes provided the cover soils are obtained from background materials that are not associated with ore formations or other radium-enriched materials.

C.2.3 Radon Emanation Coefficient

The radon emanation coefficient used in the model for the tailings is 0.20 based on laboratory data (Rogers & Associates, 1988) and the recommendation in NUREG-1620 (NRC, 2003) to use a value of 0.20 for tailings if there is limited site-specific data.

The radon emanation coefficient used in the model for the cover layers is 0.35. This is the conservative default value used in the RADON model.

C.2.4 Specific Gravity, Density and Porosity

The densities and porosities of the tailings and cover materials used in the model are based on laboratory testing results. The values are summarized in Table C.2 and discussed in more detail below.

Table C.2. Density and Porosity Values

Material	Specific Gravity	Degree of Compaction (%)	Placed Density (pcf)	Placed Density (g/cc)	Porosity
Erosion Protection (topsoil)	2.61	85% SP	100	1.6	0.38
Erosion Protection (rock mulch)*	2.62	85% SP	106	1.7	0.35
Random fill (low compaction water storage, rooting zone)	2.63	85% SP	100	1.6	0.39
Random Fill (high compaction)	2.63	95% SP	112	1.8	0.32
Random Fill (in place, low compaction, platform fill)	2.63	80% SP	94	1.5	0.43
Tailings	2.80	---	96	1.5	0.45

SP = standard proctor compaction
* Estimated by applying a 25% rock correction to the topsoil

The specific gravity of the tailings was estimated as 2.80 based as the weighted average specific gravity from laboratory tests using estimated percentages of sand, sand-slime, and slime tailings of 10, 65, and 25 percent, respectively (MWH, 2015). The dry density of the tailings was estimated as 96 pcf, based on laboratory tests (Chen and Associates, 1987 and Western Colorado Testing, 1999b) and assuming the upper bound long-term density of the tailings should be no greater than 90 percent of the average laboratory measured maximum dry density for the tailings. The referenced reports are provided as part of Appendix A.1 of MWH (2011). The porosity of the tailings was calculated using the estimated specific gravity and dry density based on the following equation:

$$n = 1 - \left(\frac{\gamma_d}{G_s \gamma_w}\right) \qquad \text{(Eq. C.1)}$$

where

n = porosity,

γ_d = dry density of soil,

G_s = specific gravity of soil, and

γ_w = unit weight of water.

The specific gravity and dry density values used in the model for the random fill layers were estimated by laboratory tests (ATT, 2010 and UWM, 2012). The referenced reports will be provided as part of Appendix A.2 of the next version of the of the Updated Tailings Cover Design report. These reports were presented in Attachment B of EFRI (2012). The estimation for the values used in the model is provided in Attachment C.2. The porosity values for the layers were calculated using equation C.1. The proposed cover system has three layers of random fill placed at different levels of compaction. The lower layer of random fill consists of a minimum thickness of 2.5 feet of random fill that is assumed to be dumped and minimally compacted by construction equipment to approximately 80 percent standard Proctor. The middle layer (3.0 – 4.0 feet) of random fill will be compacted to 95 percent of standard Proctor. In Cell 2 and parts of Cell 3, the lower layer of random fill is already placed and is approximately

3 feet. It is assumed the upper 6 inches of this fill will be part of the middle random fill layer and can be compacted by additional passes of compactors to reach 95 percent of standard Proctor compaction. The uppermost 3.5 feet of random fill will be placed at 85 percent of standard Proctor compaction in order to optimize water storage and rooting characteristics for plant growth.

The 0.5 foot erosion protection layer is assumed to be topsoil or rock mulch consisting of topsoil material mixed with 25 percent gravel by weight. The specific gravity and density of the topsoil was estimated to be 2.61 and 100 pcf, respectively, based on laboratory testing results for topsoil (UWM, 2012) The specific gravity and density of the rock mulch was estimated to be 2.62 and 106 pcf, respectively, based on laboratory testing results for topsoil (UWM, 2012) and applying a rock correction based on 25 percent gravel by weight.

C.2.5 Long-term Moisture Content

The long-term moisture content value for the tailings is assumed to be 6 percent. This is a conservative assumption, per NRC Regulatory Guide 3.64 (NRC, 1989), which represents the lower bound for moisture in western soils and is typically used as a default value for the long-term water content of tailings. Use of 15 bar water contents to estimate a long-term water content is one of the methods recommended in NRC (2003) for radon emanation modeling.

MWH collected representative samples from the on-site random fill and topsoil stockpiles for use in estimating the long-term moisture contents for the random fill and erosion protection cover layers. The laboratory results for the 15 bar water contents for these samples were used to estimate long-term water contents for the random fill and erosion protection layers.

The long-term water content of the topsoil was estimated as 5.2 percent based on the measured 15 bar gravimetric water content for a topsoil sample (E1-A) which represents the average index properties for the topsoil stockpiles (UWM, 2012). The long-term water content of the rock mulch was estimated as 4 percent based on the addition of 25 percent gravel by weight to the topsoil.

Based on the cover material gradations, the cover soils were bracketed into three groups, finer grained soils, uniform graded soils, and broadly graded soils. A weighted average procedure that accounts for the size of soil type based on the stockpile volumes was incorporated to determine the average long-term gravimetric water content for the random fill using the measured 15 bar water contents. The estimation of the long-term water content value for the cover material is provided in Attachment C.2.

The average long-term moisture contents are summarized in Table C.3.

Table C.3. Estimated Long-Term Moisture Contents

Material	Gravimetric Water Content (%)
Erosion Protection (topsoil)	5.2
Erosion Protection (rock mulch)	4.0
Random fill	6.7
Tailings	6.0

C.2.6 Diffusion Coefficient

The radon diffusion coefficient used in the RADON model can either be calculated based on an empirical relationship dependent upon porosity and the degree of saturation or input directly in the model using values measured from laboratory testing. Although laboratory test data was available for the tailings and the cover material (Rogers & Associates 1988), tests were performed at porosities and water contents different than those estimated to represent long-term conditions. Therefore, the empirical relationship presented in Rogers and Nielson (1991) was used, resulting in the calculated values summarized in Table C.4 below.

Table C.4. Estimated Radon Diffusion Coefficients

Material	Diffusion Coefficient (cm^2/s)
Erosion Protection (rock mulch)	0.0254
Random Fill (low compaction water storage, rooting zone)	0.0225
Random Fill (high compaction)	0.0160
Random Fill (in place, low compaction, platform fill)	0.0260
Tailings	0.0288

C.3 MODEL RESULTS

The radon emanation modeling results show that the designed cover systems presented in Table C.5 will reduce the rate of radon emanation to values below the limit of 20 picocuries per square meter per second (pCi/m^2-s) averaged over the entire area of the tailings impoundments, which is the regulatory criterion (Utah Administrative Code, Rule 313-24). The RADON model output is provided in Attachment C.3.

Table C.5. Summary of Results

Cover Layer	Cover Thickness (ft)		
	Cell 2	Cell 3	Cells 4A/4B
Erosion Protection (rock mulch or topsoil)	0.5	0.5	0.5
Random Fill (low compaction water storage, rooting zone)	3.5	3.5	3.5
Random Fill (high compaction)	4.0	3.5	3.0
Random Fill (in place, low compaction, platform fill)	2.5	2.5	2.5
Total Cover Thickness	**10.5**	**10.0**	**9.5**

C.4 IMPACTS OF INCREASED THICKNESS OF RANDOM FILL

Radon modeling as discussed above assumed that the lower layer of random fill was placed at 80 percent of standard Proctor compaction, and had a thickness of 2.5 feet (assuming top 6 inches can be compacted to 95 percent of standard Proctor density prior to placement of additional fill). However, there are some areas within Cells 2 and 3 which show thicknesses of existing random fill greater than 3.0 feet. Additional modeling was performed to determine the minimum thickness of highly compacted random fill required in order to meet regulatory criterion to limit the radon emanation rate through the top of the cover to 20 pCi/m^2-s. This modeling indicates that for every extra foot of low-compaction random fill (80 percent standard Proctor compaction), the highly compacted random fill layer (95 percent standard Proctor compaction) can be reduced in thickness by approximately 0.75 feet. This trend is shown in Figure C.1. The RADON model output is provided in Attachment C.4.

Calculation of Ra-226 Concentrations Due to Future Decay of Th-230

The RA-226 concentration at various times in the future depends on both the decay of the Ra-226 currently present and the ingrowth from Th-230. The Ra-226 decays with a half-life of 1602 years. The ingrowth is also a function of the Ra-226 half-life (1602 years) and the Th-230 half-life (77,000 years).

A (Ra-226) at a time t (years) = [A (Ra-226) at t=0][exp(-0.693t/1602 years)]

A (Ra-226 from decay of Th-230 at time t (years)) = [A (Th-230)][1-exp(-0.693t/1602 years)][exp(-0.693t/77,000 years)]

Soil Group[4]	Volume (cy)	Total Vol (cy)	Percent of Total Volume	Ave. Max. Dry Density (pcf)	Ave. Specific Gravity	Ave. 15bar Grav. Water Content (%)
Group B	1,728,308	3,596,621	48.1%	123	2.64	5.2
Group U	1,682,013	3,596,621	46.8%	115	2.64	7.3
Group F	186,300	3,596,621	5.2%	105	2.61	13.6
			Weighted Ave.	**118**	**2.63**	**6.7**

Notes:

1. Volumes estimated using 2009 topography and assuming a relatively flat bottom surface, except for stockpiles W5, W8 and W9. The volumes for stockpiles W8 and W9 were estimated by comparing the 2011 versus 2009 topography. The volume for stockpile W5 was estimated using a combination of both methods.
2. LL = Liquid Limt, PL = Plastic Limit, PI = Plasticity Index (PI = LL-PL)
3. Gravel = 4.75 mm to 75 mm, Sand = 0.075 mm to 4.75 mm, Fines: Silt = 0 .075 mm to 0.002 mm, Clay = less than 0.002 mm
4. Group B (broadly graded), Group U (uniformly graded), and Group F (fine textured) based on evaluation of gradations and Benson (2012). See Attachment B of EFRI (2012) for gradations and laboratory reports.

RADON FLUX, CONCENTRATION AND TAILINGS COVER THICKNESS ARE CALCULATED FOR MULTIPLE LAYERS

OUTPUT FILE: Cell2rm

DESCRIPTION: Cell 2 Cover (rock mulch on surface)

CONSTANTS

RADON DECAY CONSTANT	.0000021	s^-1
RADON WATER/AIR PARTITION COEFFICIENT	.26	
DEFAULT SPECIFIC GRAVITY OF COVER & TAILINGS	2.65	

GENERAL INPUT PARAMETERS

LAYERS OF COVER AND TAILINGS	5	
NO LIMIT ON RADON FLUX		
LAYER THICKNESS NOT OPTIMIZED		
DEFAULT SURFACE RADON CONCENTRATION	0	pCi l^-1
SURFACE FLUX PRECISION	.001	pCi m^-2 s^-1

LAYER INPUT PARAMETERS

LAYER 1 Tailings

THICKNESS	500	cm
POROSITY	.45	
MEASURED MASS DENSITY	1.5	g cm^-3
MEASURED RADIUM ACTIVITY	923	pCi/g^-1
MEASURED EMANATION COEFFICIENT	.2	
CALCULATED SOURCE TERM CONCENTRATION	1.292D-03	pCi cm^-3 s^-1
WEIGHT % MOISTURE	6	%
MOISTURE SATURATION FRACTION	.200	
MEASURED DIFFUSION COEFFICIENT	.0288	cm^2 s^-1

LAYER 2 Random Fill

THICKNESS	76	cm
POROSITY	.43	
MEASURED MASS DENSITY	1.5	g cm^-3
MEASURED RADIUM ACTIVITY	0	pCi/g^-1
MEASURED EMANATION COEFFICIENT	.35	
CALCULATED SOURCE TERM CONCENTRATION	0.000D+00	pCi cm^-3 s^-1
WEIGHT % MOISTURE	6.7	%
MOISTURE SATURATION FRACTION	.234	
MEASURED DIFFUSION COEFFICIENT	.026	cm^2 s^-1

LAYER 3 Compacted Random Fill

THICKNESS	122	cm
POROSITY	.32	
MEASURED MASS DENSITY	1.8	g cm^-3
MEASURED RADIUM ACTIVITY	0	pCi/g^-1
MEASURED EMANATION COEFFICIENT	.35	
CALCULATED SOURCE TERM CONCENTRATION	0.000D+00	pCi cm^-3 s^-1
WEIGHT % MOISTURE	6.7	%
MOISTURE SATURATION FRACTION	.377	
MEASURED DIFFUSION COEFFICIENT	.016	cm^2 s^-1

LAYER 4 ET Cover

THICKNESS	107	cm
POROSITY	.39	
MEASURED MASS DENSITY	1.6	g cm^-3
MEASURED RADIUM ACTIVITY	0	pCi/g^-1
MEASURED EMANATION COEFFICIENT	.35	
CALCULATED SOURCE TERM CONCENTRATION	0.000D+00	pCi cm^-3 s^-1
WEIGHT % MOISTURE	6.7	%
MOISTURE SATURATION FRACTION	.275	
MEASURED DIFFUSION COEFFICIENT	.0225	cm^2 s^-1

LAYER 5 Rock Mulch

THICKNESS	15	cm
POROSITY	.35	
MEASURED MASS DENSITY	1.7	g cm^-3
MEASURED RADIUM ACTIVITY	0	pCi/g^-1
MEASURED EMANATION COEFFICIENT	.35	
CALCULATED SOURCE TERM CONCENTRATION	0.000D+00	pCi cm^-3 s^-1
WEIGHT % MOISTURE	4	%
MOISTURE SATURATION FRACTION	.194	
MEASURED DIFFUSION COEFFICIENT	.0256	cm^2 s^-1

APPENDIX D

VEGETATION AND BIOTINTRUSION EVALUATION

D.1 INTRODUCTION

This appendix provides an evaluation of vegetation that would be used as an integral part of an evapotranspiration (ET) cover proposed for reclamation of tailings cells at the White Mesa Mill (Mill) site. A critical component of an ET cover is the plant community that will be established on the cover and will function over the long term to provide protection from wind and water erosion and assist in removing water through the process of transpiration. In this appendix, issues related to the short-term establishment and long-term sustainability of vegetation proposed as part of the ET cover are addressed. These issues include: plant species selection, ecological characteristics of species (i.e., longevity, sustainability, compatibility, competition, rooting depth and root distribution), characteristics of the established plant community (i.e., percent plant cover and leaf area index [LAI]), and soil requirements for sustained plant growth. Information is also presented on weed control, vegetation performance goals and criteria, and post-closure vegetation monitoring. In addition, biointrusion from both plants and animals is addressed using information from an on-site survey conducted in June 2012 and literature applicable to site conditions. Finally there is discussion on climate change projections for the performance period and possible changes that may occur with plant community composition over time.

D.2 PROPOSED SPECIES FOR ET COVER RECLAMATION

The following 15 species (11 grasses, 2 forbs, and 2 shrubs) are proposed for the ET cover system at the Mill site. These species were selected for their adaptability to site conditions, compatibility, and long-term sustainability. Species were also selected based on the assumption that institutional controls will exclude grazing by domestic livestock. The proposed species are:

- Western wheatgrass, variety Arriba (*Pascopyrum smithii*)
- Bluebunch wheatgrass, variety Goldar (*Pseudoroegneria spicata*)
- Slender wheatgrass, variety San Luis (*Elymus trachycaulus*)
- Streambank wheatgrass, variety Sodar (*Elymus lanceolatus ssp. psammophilus*)
- Pubescent wheatgrass, variety Luna (*Thinopyrum intermedium ssp. barbulatum*)
- Indian ricegrass, variety Paloma (*Achnatherum hymenoides*)
- Sandberg bluegrass, variety Canbar (*Poa secunda*)
- Sheep fescue, variety Covar (*Festuca ovina*)
- Squirreltail, variety Toe Jam Creek (*Elymus elymoides*)
- Blue grama, variety Hachita (*Bouteloua gracilis*)
- Galleta, variety Viva (*Hilaria jamesii*)
- Common yarrow, no variety (*Achillea millefolium*)
- White sage, variety Summit (*Artemisia ludoviciana*)
- Fourwing saltbush, variety Wytana (*Atriplex canescens*)
- Rubber rabbitbrush, no variety (*Ericameria nauseosus*).

These species are described in more detail later in this appendix.

D.3 PROPOSED SEEDING RATES

Given a mixture of the species listed above, Table D.1 presents broadcast seeding rates for each species. Seeding rates were developed based on the objective of establishing a permanent cover of grasses, forbs, and shrubs in a mixture that would promote compatibility among species and minimize competitive exclusion or loss of species over time. The proposed seeding rate is based on number of seeds/ft^2 and then converted to pounds of pure live seed per acre (lbs PLS/acre), with further discussion presented below.

The number of seeds placed in a unit area of soil is called the seeding rate. The total seeding rate is the sum of the individual species seeding rates. Seeding rates are normally expressed as the number of seeds per square foot or pounds per acre. Many different seeding rates for the same species can be found in the literature. The primary reason for these differences is that some rates are for monocultures and other rates are for diverse mixtures. In addition, seeding rates vary depending on the method of seeding and site conditions related to edpaphic factors, topography and climate.

Seeding rates are developed on the basis of number of seeds per unit area (e.g. number of seeds per square foot). Once this number is determined, then it can be converted to weight per unit area (e.g. pounds per acre). Since each species produces seed that weighs a different amount, the development of seeding rates based purely on weight per unit area will produce erroneous rates that will tend to over emphasize small seeded species and under-emphasize large seeded species. For example, blue grama has approximately 700,000 seeds per pound, while Indian ricegrass has approximately 175,000 seeds per pound. If seeding rates were calculated simply on the basis of weight per unit area, without recognizing the fact that a pound of blue grama seed has four times the number of seeds per pound as Indian ricegrass, it would be very easy to over plant blue grama and under plant Indian ricegrass.

Table D.1. Species and Seeding Rates Proposed for ET Cover at the Mill Site

Scientific Name	Common Name	Varietal Name	Native/ Introduced	Seeding Rate (lbs PLS/acre)†	Seeding Rate (# seeds/ft^2)
Grasses					
Pascopyrum smithii	Western wheatgrass	Arriba	Native	3.0	7.9
Pseudoroegneria spicata	Bluebunch wheatgrass	Goldar	Native	3.0	9.6
Elymus trachycaulus	Slender wheatgrass	San Luis	Native	2.0	6.2
Elymus lanceolatus	Streambank wheatgrass	Sodar	Native	2.0	7.3
Elymus elymoides	Squirreltail	Toe Jam	Native	2.0	8.8
Thinopyrum intermedium	Pubescent wheatgrass	Luna	Introduced‡	1.0	1.8
Achnatherum hymenoides	Indian ricegrass	Paloma	Native	4.0	14.7
Poa secunda	Sandberg bluegrass	Canbar	Native	0.5	11.4
Festuca ovina	Sheep fescue	Covar	Introduced‡	1.0	11.5
Bouteloua gracilis	Blue grama	Hachita	Native	1.0	16.5
Hilaria jamesii	Galleta	Viva	Native	2.0	7.3
Forbs					

Scientific Name	Common Name	Varietal Name	Native/ Introduced	Seeding Rate (lbs PLS/acre)†	Seeding Rate (# seeds/ft^2)
Achillea millefolium, variety occidentalis	Common yarrow	VNS*	Native	0.5	32
Artemisia ludoviciana	White sage	VNS	Native	0.5	45
Shrubs					
Atriplex canescens	Fourwing saltbush	Wytana	Native	3.0	3.4
Ericameria nauseosus	Rubber rabbitbrush	VNS	Native	0.5	4.6
Total				26.5	188

†Seeding rate is for broadcast seed and presented as pounds of pure live seed per acre (lbs PLS/acre).
‡Introduced refers to species that have been 'introduced' from another geographic region, typically outside of North America. Also referred to as 'exotic' species. *VNS=Variety Not Specified but seed source would be designated from sites similar to the Mill site.

Seeding rate may be calculated from an expected field emergence for each species and the desired number of plants per unit area. For purposes of calculation, field emergence for small seeded grasses and forbs is assumed to be around 50 percent if germination is greater than 80 percent. Field emergence is assumed to be around 30 percent if germination is between 60 and 80 percent. The Natural Resource Conservation Service recommends a seeding rate of 20 to 30 pure live seeds per square foot as a minimum number of seeds when drill seeding single species in areas with an annual precipitation between 6 and 18 inches. Twenty pure live seeds per square foot, with an expected field emergence of 50 percent should produce an adequate number of plants on the seeded area to control erosion and suppress annual invasion. This seeding rate is primarily for favorable growing conditions, soils that are not extreme in texture, gentle slopes, north or east facing aspect, good moisture, adequate soil nutrients and single species vs. multiple species in a mixture. When conditions are less favorable when the seed is broadcast, or when multiple species are in a mixture the seeding rates are increased.

A Quality Assurance/Quality Control Plan for application rates and procedures for confirming that specified application rates are achieved is as follows. The first step begins with a seed order. Seed would be purchased as pounds of pure live seed. Each State has a seed certifying agency and certification programs may be adopted by seed growers. Certification of a container of seed assures the customer that the seed is correctly identified and genetically pure. The State agency responsible for seed certification sets minimum standards for mechanical purity and germination for each species of seed. When certified, a container of seed must be labeled as to origin, germination percentage, date of the germination test, percentage of pure seed (by weight), other crop and weed seeds, and inert material. The certification is the consumer's best guarantee that the seed being purchased meets minimum standards and the quality specified.

Once the seed is obtained, seed labels would be checked to determine the percent PLS and the date that the seed was tested for percent purity and percent germination. If the test date is greater than 6 months old, the seed would be tested again before being accepted. Seed will be applied using a broadcasting method. This procedure would use a centrifugal type broadcaster (or similar implement)), also called an end-gate seeder. These broadcasters operate with an electric motor and are usually mounted on the back of a small tractor and generally have an effective spreading width of about 20 feet or more. Prior to seeding, a known area will be covered with a tarp and seed will be distributed using the broadcaster and simulating conditions that would exist under actual seeding conditions. Seed will then be collected and weighed to determine actual seeding rate in terms of pounds per acre. This process will be repeated until the specified seeding rate is obtained. During the seeding process, the seeding rate will be verified at least once by comparing pounds of seed applied to the size of the area seeded. In addition, seed will be applied in two separate passes. One-half of the seed will be spread in one direction and the other half of seed will be spread in a perpendicular direction. This will ensure that seed distribution across the site is highly uniform and also provide the opportunity to adjust the seeding rate if the specified rate is not being achieved.

D.4 ECOLOGICAL CHARACTERISTICS OF PROPOSED SPECIES AND ESTABLISHED PLANT COMMUNITY

D.4.1 Ecological Characteristics of Plant Species of Tailings Cover System

Important ecological characteristics for each species proposed for reclamation are provided in the paragraphs that follow. Species information was obtained from a number of references that are cited below. The proposed species are adapted to the elevation (5,600 feet), precipitation (13 inches per year on average), and soil textural ranges (loam to sandy clay) that are well within the environmental conditions of the Mill site. Table D.2 presents a summary of the ecological characteristics discussed in the following paragraphs.

Western wheatgrass, variety Arriba (*Pascopyrum smithii*) – Western wheatgrass is a native, rhizomatous, long-lived perennial cool season grass. It grows well in a 10- to 14-inch mean annual precipitation zone and is adapted to a wide range of soil textural classes at elevation ranges up to 9,000 feet. Western wheatgrass has been an important species for restoring mining related disturbances, for erosion control and for critical area stabilization in semi-arid regions because of its ease of establishment and ability to grow successfully in pure or mixed stands of both warm and cool season species. Western wheatgrass is fire tolerant and regenerates readily following burning. The variety of Arriba is known for rapidly establishing seedlings and high seed production. The combination of its ability to spread vegetatively and reproduce by seed ensures long-term sustainability of this species.

Bluebunch wheatgrass, variety Goldar (*Pseudoroegneria spicata*) – Bluebunch wheatgrass is a native, cool season perennial bunch grass. Bluebunch wheatgrass grows on soils that vary in texture, depth and parent material. It is one of the most important and productive grasses found in sagebrush communities in the intermountain west. Bluebunch wheatgrass is fire tolerant and regenerates vegetatively following burning. This species is well adapted to a 12- to 14-inch mean annual precipitation range and is considered to be highly drought resistant. Bluebunch wheatgrass performs well in mixtures with other species and grows at elevations up to 10,000 feet.

Slender wheatgrass, variety San Luis (*Elymus trachycaulus*) – Slender wheatgrass is a native, cool season, perennial bunch grass that occasional produces rhizomes. It is a short-lived species (5 to 10 years) but it reseeds and spreads well by natural seeding, exceeding most other wheatgrasses in this characteristic. Slender wheatgrass can serve as an important pioneer species; its seedlings are vigorous and capable of establishing on harsh sites. In addition, it is able to establish and compete with weedy species. Slender wheatgrass is commonly seeded in mixtures with other grasses and forbs to restore disturbances and rehabilitate native communities. It is adapted to a wide variety of sites and is moderately drought tolerant. It performs best at sites with an annual precipitation of 15 inches or more, but can grow on sites with precipitation levels as low as 13 inches.

Table D.2. Summary of Ecological Characteristics of Plant Species Proposed for the ET Cover at the Mill Site

Species	Origin	Annual or Perennial	Method of Spread	Ease of Establishment[a]	Compatibility with Other Species[a]	Longevity[a]	Annual Precipitation Range (inches)	Elevation Range (feet)	Soil Texture[b]	Rooting Depth (cm)	Soil Stabilization[a]	Drought Tolerance[a]	Fire Tolerance[a]

[k]Monsen et al., 2004.

Streambank wheatgrass, variety Sodar (*Elymus lanceolatus* ssp. *psammophilus*) – Streambank wheatgrass is considered to be part of the thickspike wheatgrass (*Elymus lanceolatus* ssp. *lanceolatus*) taxa. Variety Sodar is a native, perennial sod grass that is highly rhizomatous and adapted to the western intermountain area. It is highly drought tolerant and performs well in mean annual precipitation ranges between 11 and 18 inches. It grows on a wide range of soil textures, from sandy to clayey. Streambank wheatgrass is commonly used in mine land reclamation and is best known for its ability to control erosion and compete with annual weeds. Its highly rhizomatous nature ensures long-term sustainability of this species.

Pubescent wheatgrass, variety Luna (*Thinopyrum intermedium* ssp. *barbulatum*) – Pubescent wheatgrass is a long-lived sod forming perennial introduced from Eurasia. It is highly drought tolerant and grows where the mean annual precipitation is 12 inches or more. It is adapted to a wide range of soil textures, from sand to clay. Pubescent wheatgrass is a highly persistent species, should be seeded at low densities to avoid competition with native species.

Indian ricegrass, variety Paloma (*Achnatherum hymenoides*) – Indian ricegrass is a native, cool season, perennial bunchgrass with a highly fibrous root system. Indian ricegrass is one of the most common grasses on semi-arid lands in the west and is one of the most drought tolerant species used in mine land reclamation. It generally occurs on sandy soils, but is found on soils ranging from sandy to heavy clays. It grows from 2,000 to 10,000 feet in areas where the mean annual precipitation is 6 to 16 inches. Indian ricegrass is slow to establish, but highly persistent once it becomes established.

Sandberg bluegrass, variety Canbar (*Poa secunda*) – Sandberg bluegrass is a native, cool season perennial bunchgrass that is adapted to all soil textures and is highly resistant to fire damage. Sandberg bluegrass is one of the more common early-season bunchgrasses in the Intermountain area. It grows at elevations from 1,000 to 12,000 feet and can be successfully established in areas with a mean annual precipitation of 12 inches or more. Established plants are not overly competitive, and therefore highly compatible with other native species.

Sheep fescue, variety Covar (*Festuca ovina*) – Sheep fescue is a short, mat-forming introduced perennial that grows well on infertile soils in areas with a mean annual precipitation of 10 to 14 inches. It is long-lived and highly drought tolerant. Sheep fescue is a cool season species that greens up early in the spring. The proposed variety, Covar, was introduced from Turkey and is commonly used in mine land reclamation for long-term stabilization and erosion control. This variety was selected because plants are persistent, winter hardy, and drought tolerant.

Squirreltail, variety Toe Jam Creek (*Elymus elymoides*) – Squirreltail is a short-lived perennial that is selected for its ability to establish quickly and to effectively compete with undesirable annual grasses. It grows along an elevation range from 2,000 to 11,000 feet and on all soil textures in mean annual precipitations zones of 8 to 15 inches. Squirreltail is fairly tolerant of fire because of its small size.

Blue grama, variety Hachita (*Bouteloua gracilis*) – Blue grama is a low-growing perennial warm season bunchgrass. Blue grama produces an efficient, widely spreading root system that is mostly concentrated near the soil surface. Blue grama is adapted to a variety of soil types, but does best on well-drained soils and once established, is highly drought tolerant. This species is commonly found with cool-season species and is highly compatible with other native perennials.

Galleta, variety Viva (*Hilaria jamesii*) – Galleta is a strongly rhizomatous perennial warm season grass with a dense, fibrous root system. Galleta grows on sits receiving 6 to 18 inches of annual precipitation with soils ranging from coarse to fine. Plants have a low requirement for soil fertility and are drought and fire tolerant.

Common yarrow (*Achillea millefolium, var. occidentalis*) – Yarrow is a common native forb species that is rhizomatous and found growing from valley bottoms to timberline. It is commonly used in mine land reclamation, establishes easily from seed and is highly persistent. It grows on a variety of soil textures and found in a mean annual precipitation range between 13 and 18 inches. If seed is not available for *Achillea millefolium* var. *occidentalis*, then the introduced *Achillea millefolium* would be used, which has the same growth characteristics as the native form.

White sage, variety Summit (*Artemisia ludoviciana*) – White sage is considered to be a pioneer rhizomatous forb species that establishes quickly on disturbed sites and is highly compatible with perennial grasses. It does best on well-drained soils, but can be found growing on a wide range of soil textures. It is adapted to sites above 5,000 feet in elevation and to sites with a mean annual precipitation above 12 inches.

Fourwing saltbush, variety Wytana (*Atriplex canescens*) – Fourwing saltbush can be deciduous or evergreen, depending on climate. Its much-branched stems are stout and mature plants range from 1 to 8 feet in height, depending on ecotype, the soil, and climate. Fourwing saltbush is one of the most widely distributed and important native shrubs on rangelands in the western United States. Fourwing saltbush is highly palatable browse and is utilized primarily in the winter at which time it is high in carotene and digestible protein. Fourwing saltbush provides excellent season long browse for deer. It is a good browse plant for antelope and elk in fall and winter. It is also a food source and excellent cover for upland birds. Fourwing saltbush has excellent drought tolerance. Fourwing saltbush is adapted to most soils but is best suited to loamy to sandy to gravely soils. It is not especially tolerant of fire, but may re-sprout to some degree if fire intensity is not too severe. Fourwing saltbush occurs most commonly in salt-desert scrub communities in the desert areas of western North America in areas that receive 8 to 14 inches of annual precipitation. It can be found from sea level in Texas to over 8,000 feet in Wyoming.

Rubber rabbitbrush (*Ericameria nauseosus*) – Rubber rabbitbrush is a native, perennial, warm-season shrub that grows to 1 to 8 feet tall. Rubber rabbitbrush is an important browse species for wildlife during the winter months. Rubber rabbitbrush occurs as a dominant to minor component in many plant communities, ranging from arid rangelands to montane openings. It thrives in poor conditions, and can tolerate coarse, alkaline soils. Dense stands are often found on degraded rangelands, along roadsides, and in abandoned agricultural fields. The species is useful in soil stabilization and restoration of disturbed sites. The root system establishes quickly and plants produce large quantities of leaf litter. Rubber rabbitbrush is adapted to cold, dry environments receiving 7 to 18 inches of annual precipitation at elevations ranging from 450 to 8,000 feet. Depending on the ecotype, rubber rabbitbrush can be found on loamy, sandy, gravelly or heavy clay soils that are slightly acidic, slight to strongly basic, or saline.

D.4.2 Longevity and Sustainability

All of the species proposed for reclamation of the tailings cells are long-lived, except for slender wheatgrass (*Elymus trachycaulus*) and squirreltail (*Elymus elymoides*). Slender wheatgrass is a perennial bunchgrass that is short-lived (5 to 10 years) but has the ability to reseed and spread vegetatively with rhizomes. Squirreltail is also a short-lived perennial but has the ability to establish quickly and is highly effective in competing with undesirable annual grasses. Both of these species are included in the proposed seed mixture because of their ability to provide quick cover for erosion protection and to effectively compete with annual and biennial species that cannot be relied upon to provide consistent and sustainable plant cover. The use of these species will facilitate the establishment of the remaining long-lived perennials that have been documented to be highly adapted to the elevation, climate, and soil conditions found at the Mill site (Monsen et al., 2004; Alderson and Sharp, 1994; Wasser, 1982; Thornburg, 1982).

The perennial grasses, forbs, and shrubs in the proposed seed mixture include species that develop individual plants that are long lived (30 years or more) and are able to reproduce either by seed or vegetative plant parts like rhizomes and tillers. The use of these species in reclamation of the tailings cells will ensure a permanent or sustainable plant cover because of the highly adapted nature of these species to site conditions, their tolerance to environmental stresses such as drought, fire, and herbivory, and their ability to effectively reproduce over time.

The use of a mixture of species for the ET cover also contributes to longevity and sustainability. The establishment of a diverse community has many advantages over a monoculture for sustained plant growth. The use of a variety of species ensures that diverse microsites that may exist over a seeded site are properly matched with species that are adapted to those specific environmental conditions. In addition, a mixture of species reverses the loss of plant diversity and enhances natural recovery processes following impacts from insects, disease organisms, and adverse or changes in climatic conditions. Finally, mixtures provide improved ground cover and surface stability, along with reducing weed invasion by fully utilizing plant resources such as water, nutrients, sunlight and space. Weeds in this context are typically annual or biennial plants considered to be undesirable, especially growing where they are not wanted.

D.4.3 Compatibility

Reclamation research and its application have been ongoing in the U.S. since the early 1900s. First with the reseeding of millions of acres following the dust bowl of the 1930s. Then, improvements of large tracts of arid and semi-arid rangelands between the 1960s and 1980s following more than a half a century of rangeland exploitation through overgrazing. In 1985 the U.S. Department of Agriculture Conservation Reserve Program was implemented which resulted in the conversion of more than 40 million acres of marginal farm land to permanent grasslands through an extensive seeding program. Finally, there have been tens of thousands of acres of mined lands reclaimed across the U.S. with the implementation of federal and state rules and regulations governing mine land reclamation. Over this time period, there have been thousands of reclamation publications in the form of books, scientific journal articles, symposium proceedings, and government publications. Many publications have reported on the performance of individual species and mixtures of species under semi-arid conditions similar to southeastern Utah (e.g., Plummer et al., 1968; Monsen et al., 2004). All of this work has led to a knowledge base about species compatibility. Species that are seeded together in mixtures must be compatible as young, developing plants or certain individuals will succeed and others will fail. The species proposed for the ET cover at the Mill site are all compatible with each other and seeding rates will be used to prevent overseeding species that may be aggressive [e.g., pubescent wheatgrass (*Thinopyrum intermedium*)] and could potentially dominate the site (Monsen et al., 2004). These species are commonly seeded together and many studies have shown excellent interspecies compatibility (e.g., DePuit et al., 1978; DePuit, 1982; Redente et al., 1984; Sydnor and Redente, 2000; Newman and Redente, 2001). Finally, to increase compatibility and to reduce competition among seeded species, sites would be broadcast seeded as opposed to drill seeded. According to Monsen et al. (2004), drill seeding causes species in a mixture to be placed in potentially competitive situations, while broadcasted seeds are not placed in as close contact with each other as with drilling and therefore are less likely to be negatively impacted from competition.

D.4.4 Competition

There are two ways to view competition. In the context of establishing an ET cover on the tailings cells, the use of seeded species to compete with weeds is a desirable attribute. However, competition among seeded species with the potential loss of any of these species is undesirable. Therefore, as stated earlier, the proposed seed mixtures is comprised of species that can coexist and also fully utilize plant resources to minimize weed species establishment and excluding seeded species. The establishment of weeds, especially invasives (i.e., non-native species whose introduction causes economic and environmental harm) is unacceptable because of the potential loss of seeded perennial species and the subsequent reduction in species diversity, plant cover, and overall sustainability. Once established, the proposed seed mixture will produce a grass-forb-shrub community of highly adapted and productive species that will effectively compete with undesirable species.

D.4.5 Plant Cover

Monitoring of an alternative cover at the Monticello, Utah, Uranium Mill Tailings Disposal Site showed that the plant cover performed well over a seven year period. Plant cover ranged from 5.5 percent during the first growing season to nearly 46 percent in the seventh growing season (Waugh et al., 2008). Using results from the 2007 vegetation monitoring report (DOE, 2008) the following contributions to relative cover were reported showing that 6 of the 16 species seeded provided 70 percent or more of the cover when cover differences between reclamation zones is averaged: big sagebrush—5 percent to 10 percent; rubber rabbitbrush—5.3 percent to 17 percent; western wheatgrass—38.6 percent; cicer milkvetch—11 percent; thickspike wheatgrass—7.2 percent; and globemallow—0.1 to 0.2 percent.

Approximately 40 percent of the species proposed for the Mill site were seeded at Monticello and of the six best-performing species, three of these species are in the White Mesa mixture (i.e. *Pascopyrum smithii, Elymus lanceolatus,* and *Ericameria nauseosus*). Highly competitive species used at Monticello that are not proposed for White Mesa include three introduced species (i.e. smooth brome, crested wheatgrass, and alfalfa) that were not considered acceptable for the Mill site. Based on these results and the similarity in environmental conditions between Monticello and White Mesa, a plant cover estimate of 40 percent was determined to be a reasonable estimate for a long-term average, while a percent plant cover of 30 percent was assigned as a reduced performance scenario. The percent vegetative cover at White Mesa is expected to be slightly less than what would be found at Monticello because the average annual precipitation at White Mesa is approximately 13 inches compared to 15 inches at Monticello and the average annual maximum/minimum air temperatures are 64/37°F for White Mesa and 59/33°F for Monticello. The slightly greater precipitation and lower temperatures at Monticello are due to its slightly higher elevation of 7,000 feet compared to 5,600 feet at White Mesa.

A map of current vegetation at the Mill site does not exist. The most recent mapping of vegetation at the Mill site was conducted by Dames and Moore in 1977 (Dames and Moore 1978) as part of the Environmental Report for the White Mesa Uranium Project. In 1977, the major mapping units for the project site were: big sagebrush (232 acres), controlled big sagebrush (567 acres), and reseeded grassland (369 acres). In June 2012 the area surrounding the Mill site was surveyed for plant community composition and cover in response to Interrogatory 11/1: Vegetation and Biointrusion Evaluation and Revegetation Plan of DRC (2012). There are two principal plant community types in the vicinity of the Mill site. These plant communities are Big Sagebrush shrubland and Juniper woodland. The Dames and Moore Environmental Report (1978) classified the Juniper woodland as a Pinyon-Juniper community type, but the primary tree species is Utah juniper (*Juniperus osteosperma*) and the presence of pinyon pine (*Pinus edulis*) is so infrequent that the community may be more appropriately classified as a Juniper woodland. In addition to these two principal plant community types, there are a number of disturbed areas that are in different stages of successional development and reflect past disturbances such as sagebrush removal (chaining and plowing) and seeding and intense grazing as evidenced by a complete lack of any understory species in some areas. The vegetation survey conducted in 2012 provides information of species that exist on the Mill site and their relative importance in terms of plant cover. All areas surveyed in 2012 show that big sagebrush (*Artemisia tridentata*) is the dominant species and subdominants are either broom snakeweed (*Gutierrezia sarothroae*) or galleta (*Hilaria jamesii*). If the area were re-mapped, most of the site would map as Big Sagebrush association. It appears that areas that were reseeded to crested wheatgrass and areas where controlled measures were applied to remove big sagebrush have returned to big sagebrush following seeding and/or control measures implemented sometime prior to 1978.

The Big Sagebrush shrubland is dominated by big sagebrush (*Artemisia tridentata*) with interspersed shrubs of broom snakeweed (*Gutierrezia sarothroae*) pale desert-thorn (*Lycium pallidum* var. *pallidum*), and rubber rabbitbrush (*Ericameria nauseosa*). The understory is mostly grasses with an infrequent occurrence of forbs. The grasses include galleta (*Hilaria jamesii*), squirreltail (*Elymus elymoides*), Indian ricegrass (*Achnatherum hymenoides*), and cheatgrass (*Bromus tectorum*). Forb species include scarlet globemallow (*Sphaeralcea coccinea*), lesser rushy milkvetch (*Astragalus convallarius*), and Russian thistle (*Salsola kali*).

The Juniper woodland occurs on shallow soils along the canyon rim to the east and west of the site. It is highly unlikely that this community type would expand its range into the deep, very fine sandy loam soil that occurs on the Mill site, which is the primary soil type supporting the Big Sagebrush shrubland. The vegetation sampling that was conducted in 2012 focused on the Big Sagebrush community and did not include the Juniper woodland because of the unlikely probability that this community type would ever establish on the Mill site or tailings cell cover system. A reconnaissance level survey was conducted in the Juniper community to observe both plant and animal species that occupy these areas.

D.4.6 2012 Plant Survey

The big sagebrush community type within the White Mesa Control Area to the north, south, and west of the restricted area of the mill and tailings facilities was surveyed using randomly placed transects and estimating cover by species using a point intercept sampling method (see Figure D.1). Along each 100 m long transect, live plant cover by species was determined by lowering a pin at 1 meter intervals and recording the plant species or ground cover (litter and bareground) that intersected the point. A total of 10 transects were sampled in each of the areas to the north, south and west of the mill and tailings cells. Table D.3 presents a summary of the vegetation survey conducted in the areas surrounding the mill and tailings cells. Tables D.4 through D.33 present plant cover data by transect for each of the three areas sampled in 2012.

Results from the 2012 sampling of the Big Sagebrush community surrounding the Mill site showed a mean live plant cover of 37.8 percent after averaging live plant cover estimated in areas north, south and west of the Mill site (Table D.3). This plant cover included an average of 23.1 percent cover for shrubs, 13.7 percent cover for grasses, and 1.0 percent cover for forbs. In addition, the average percent litter was 13.1 percent and bareground averaged 49.1 percent. These cover estimates are somewhat greater than the cover values reported in Dames and Moore Environmental Report (1978). In the Environmental Report, the average live plant cover in the Big Sagebrush community was 33.3 percent. This cover included an average of 19.4 percent for shrubs and 13.8 percent for grasses. Litter was estimated at 16.9 percent and bareground was 49.9 percent. Annual precipitation in 1977 was 23.6 cm compared to a long-term average of 29.7 cm (Dames and Moore 1978). In addition, monthly precipitation during the period May-September 1978 totaled 3.8 cm compared to a long-term average of 12.5 cm for the same period. Considering the fact that the areas sampled are currently grazed, it is highly likely that a cover of 40 percent can be achieved and maintained on the tailings cell cover system for conditions that exclude grazing by livestock. The formation of desert pavement and potential impact on plant cover has been raised as an issue for discussion. Desert pavements are armored surfaces composed of angular or rounded rock fragments, usually 2 to 3 cm thick, set on or in a matrix of finer material (Cooke and Warren, 1973). These surfaces form on arid soils through deflation of fine material by wind or water erosion due to a lack of protection by surface vegetation (Cooke and Warren, 1973). Desert pavements are not common in semi-arid regions and do not occur where either wind or water erosion are controlled by plant cover (Hendricks, 1991), as would be the case for the White Mesa cover system. In addition, there is no evidence of desert pavement formation either on the Mill site or areas surrounding the site (which was confirmed during the 2012 plant survey). Even with the use of a topsoil layer amended with gravel, there is no supporting evidence to indicate a potential for desert pavement formation or an associated decrease in plant cover over the long term.

D.4.7 Leaf Area Index

Monthly leaf area index (LAI) values were estimated for the proposed ET cover at the Mill site. Three primary publications were used to estimate monthly LAI for the ET cover, including: Groeneveld (1997), Scurlock et al. (2001), and Fang et al. (2008). Table D.34 presents a compilation of LAI values based on North American data sets that were focused on semi-arid herbaceous plant communities. Scurlock et al. (2001) presented mean LAI values for 15 biomes/land cover classes that included desert, grassland, and shrubland. Leaf Area Index data was a compilation of data from the literature and represented various data collection methods. Mean LAI values reported were 1.3 (S.D. 0.85) for desert, 2.6 (S.D. 3.0) for grassland, and 2.1 (S.D. 1.6) for shrubland. Fang et al. (2008) presented LAI data for various biomes using MODIS (Moderate Resolution Imaging Spectroradiometer). These authors reported monthly LAIs for grasslands and shrublands with peak values for shrubland reported at 1.5 and 1.0 for grasslands. Finally, Groeneveld (1997) conducted field measurements of LAI in Owens Valley, CA in 1983. He reported LAI values for individual grass and shrub species and reported the following values in November for big sagebrush and in July for the remaining species: big sagebrush LAI's ranged from 0.65 to 1.8; fourwing saltbush (*Atriplex canescens*) LAI's ranged from 1.2 to 4.7; shadscale saltbush (*Atriplex confertifolia*) LAI's ranged from 1.6 to 2.6; greasewood (*Sarcobatus vermiculatus*) LAI's ranged from 1.0 to 3.3; alkali sacaton (*Sporobolus airoides*) LAI's ranged from 0.38 to 4.0; and saltgrass (*Distichlis spicata*) LAI's ranged from 0.67 to 3.9. All of the data presented in these three papers was used to estimate an average monthly LAI for the revegetated cover system assuming a well-established plant community. A maximum LAI of 2.6 was selected for peak biomass in the month of September which matches the mean grassland LAI reported by Scurlock al. (2001) and well below values reported by Groeneveld (1997). Leaf Area Index values for the remaining months was then extrapolated from the peak month using monthly values presented by Fang et al. (2008). It is important to note that the proposed species for the ET cover include both cool- and warm-season species. This combination of species will maximize the length of the growing season and transpiration from early spring to late fall. Cool-season species are more productive and use more water during the cooler times of the growing season, while warm-season species are more productive and use more water during the warmest period of the year.

Table D.34. Leaf Area Index for the ET Cover at Mill Site

Month											
Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec

D.4.8 Project Root Biomass for Infiltration Modeling

We have chosen to use root biomass data from a seeded site in Cheyenne, Wyoming that was seeded in the 1950s with root biomass data collected about 35 years after seeding (Redente et al. 1989). Data were collected as g/m^2 and will not be converted (Table D.35). Infiltration model uses a normalized root density function, so root measurement units are irrelevant. The climatic conditions between Blanding, Utah and Cheyenne, Wyoming are similar with Blanding receiving 34 cm of precipitation and Cheyenne receiving 36 cm. Potential evapotranspiration (PET) at Blanding is 122 cm and 115 cm in Cheyenne. Finally, the precipitation to PET ratio is 0.28 for Blanding and 0.31 for Cheyenne. Table D.35 presents both anticipated root biomass and reduced biomass that is calculated based on a 75 percent reduction in biomass that has been reported in long-term drought studies (Weaver and Albertson 1936).

Table D.35. Projected root biomass data for anticipated and reduced performance for use in infiltration modelling

Depth (cm)	Root Biomass (g/m^2) Anticipated Performance	Root Biomass (g/m^2) Reduced Performance†
0-5	160	64
5-10	140	49
10-20	76	23
20-60	125	32
60-100‡	52	2

†Based on an increasing percent reduction from 60% to 80% with depth, as extended drought or reduced precipitation with potential climate change would result in less deep infiltration and therefore greater negative effect on deeper roots compared to shallower roots. ‡Maximum rooting depth under the reduced performance scenario would be 68 cm.

D.5 BIOINTRUSION

D.5.1 Plant Intrusion

Table D.36 presents percent of root mass by depth for grass and shrub species that exist or may occur on the Mill site during the performance period. It is extremely important to recognize that the rooting depths for the shrubs do not reflect the rooting depths that are expected in the cover system but represent rooting depths reported in the literature with an effort to identify the maximum rooting depths reported. Detailed rooting depth studies are rare and the majority of studies do not report root mass by depth. The shrub values reported in Table D.36 represent extrapolations from the literature using the maximum rooting depths reported and following the general findings in the literature that the majority of root growth typically is in the upper 30 cm for grasses and the upper 60 cm for shrubs growing in semiarid regions. The final note of importance that relates to the cover system is that root growth is strongly influenced by the soil which the root is growing and therefore root data from the literature must be carefully scrutinized as it is applied to specific site conditions (Munshower 1995). The shrub root data shown in Table D.36 should therefore not be interpreted to represent the expected rooting depths in the cover system since rooting depth will be controlled by the highly compacted radon attenuation layer within the cover system.

Soil texture appears to be the most important soil property determining the growth-limiting bulk density of a soil because of the effect of texture on soil pore size and mechanical resistance. A soil with a large amount of fine particles (silt and clay) will have smaller pore diameters and a higher penetration resistance at a lower bulk density than a soil with a large amount of coarse particles (sand size). Zisa et al. (1980) reported a silt loam soil had 19 percent macropore space and a measured penetration resistance of 2.5 bars at a bulk density of 1.4 g/cm^3. A coarser sandy loam soil had 28.9 percent macropore space and a penetration resistance of 1.2 bars at the same bulk density.

Roots grow in soil through large soil pores and by moving soil particles aside when the roots penetrate pores that are smaller than the root tips. When a soil is compacted to a growth-limiting level, most soil pore diameters are substantially smaller than the diameters of growing roots. In this situation, root growth is essentially halted because the roots cannot exert enough pressure to overcome the mechanical resistance and move soil particles. Other pertinent studies that relate root growth and bulk density include articles by Siegel Issem et al. 2005, Mimore and Woollard 1969, and Heilman 1981.

Most, if not all, of the root growth studies cited above that relate root growth to soil compaction and soil bulk density are field studies in native soils that have been in place for centuries or longer. These soils have therefore gone through countless wetting and drying cycles and freeze-thaw cycles and still maintain certain bulk densities that impede root growth.

Table D.36. Percent of root mass by depth for grasses and shrub species that exist or may occur at the Mill site during the performance period of 200 years.

Species	0-30 cm	30-60 cm	60-90 cm	90-120 cm	120-150 cm

Shadscale[c]	15	20	18	14	12	8	6	4	2	1
Blackbrush[d]	35	50	15	--	--	--	--	--	--	--
Mormon tea[e]	20	35	17	13	10	4	1	--	--	--

[a]Tabler 1964; [b]Gibbens and Lenz 2001; [c]Kearney et al 1960; [d]West 1983; Manning et al. 1990;
[e] Gibbens and Lenz 2001;[f]beyond maximum rooting depth reported in the literature

It is important to note that shrub rooting depths reported in the literature do not reflect expected rooting depths in the cover system because of the presence of a highly compacted radon attenuation layer.

D.5.2 Animal Intrusion

The Dames and Moore Environmental Report (1978) included animal surveys for sites surrounding the Mill site. The Environmental Report recorded the presence or possible presence of a number of burrowing species in the Big Sagebrush community, including burrowing owl (*Bubo virginianus*), pocket mouse (*Perognathus* sp.), kangaroo mouse (*Microdipodops* sp.), vole (*Microtus* sp.), desert cottontail (*Sylvilagus audubonii*), coyote (*Canis latrans*), red fox (*Vulpes vulpes*), striped skunk (*Mephitis mephitis*), badger (*Taxidea taxus*), longtail weasel (*Mustela frenata*), and Gunnison prairie dog (*Cynomys gunnisoni*). Additional burrowing animals reported to occur in the Juniper community included pinyon mouse (*Peromyscus truei*) and deer mouse (*Peromyscus maniculatus*). The northern pocket gopher (*Thomomys talpoides*) was not observed in either community type and no mention of the species is made in the 1978 report.

D.5.3 2012 Burrowing Animal Survey

In June 2012 the area surrounding the Mill site was surveyed for burrowing animals in response to Interrogatory 11/1. A total of 100 km of transects were walked in Big Sagebrush and Juniper communities surrounding the Mill Site to determine either the presence of burrowing animals or future colonization based on existing habitat characteristics (see Figure D.2).

Transects were arranged in a systematic manner (at each location in Figure D.2) with a 50 m spacing between transects and transect lengths running between 100 and 400 m, depending upon physiographic features on the landscape. The primary focus of the survey was on three species that would potentially represent the deepest potential for burrows on the tailings cells during the performance period. These species included the badger, Gunnison prairie dog, and northern pocket gopher. Observations were made along each transect for animal sightings, animal presence in the form of tracks, scat or active burrows, burrow densities, and habitat characteristics.

During the animal survey one badger sighting was made and multiple active prairie dog colonies were observed to the north of the mill complex. There appears to be suitable habitat for the northern pocket gopher in the sagebrush communities surrounding the Mill site, but there is no indication that a population of northern pocket gophers occurs in the vicinity of the Mill site. There were no evidence of pocket gophers during surveys associated with the Environmental Report (Dames and Moore, 1978) and no evidence of pocket gophers 34 years later.

An attempt was made to estimate burrow densities for badgers but it was not always possible to confirm a badger burrow. No badger feeding areas (i.e. dug-out prey burrows) were observed along transects that were traversed. The reported burrow density for badgers may or may not be low, depending upon how active badgers are in the area. One of the seminal studies on badger ecology was conducted by Messick and Hornocker (1981) in southwestern Idaho. The authors reported badger densities of 159/50 km^2. This converts to approximately three per 100 hectares. Our survey reported the highest burrow densities at one per 80 to 100 hectares. If each burrow represented more than one individual badger, the densities potentially would be greater. Regardless, the reported burrow densities from the 2012 survey are believed to be a realistic estimate of badger presence at the Mill site.

Within the prairie dog colonies that were located in the area of the Mill site, the greatest burrow density was estimated at 148 burrows per hectare. Over the entire Mill site the prairie dog burrow density ranges from 0 to 148 burrows per hectare. Lupis et al. (2007) reported densities of active burrows in southeastern Utah in the range of 41 to 131/hectare or an average of 75 active burrows per hectare. The burrow densities reported from out 2012 survey are well within the range of a much larger study conducted by Lupis et al. (2007).

Lupis et al. (2007) provide a list of species in grasslands and shrublands in Utah considered primary and secondary habitat for the Gunnison's prairie dog as follows:

> "Perennial and annual Grasslands; or herbaceous dry meadows, including mostly forbs and grasses occurring at 640-2,740 m (2,200-9,000 ft) elevation. Principal perennial grass species include: bluebunch wheatgrass, sandburg bluegrass (Poa secunda), crested wheatgrass (Agropyron cristatum), basin wildrye (Elymus cinereus), galleta (Pleuraphis jamesii), needlegrass (Achnatherum hymenoides), sand dropseed (Sporobolus cryptandrus), blue grama (Bouteloua gracilis), Thurbers needlegrass (Achnatherum thurberianum), western wheatgrass (Pascopyum smithii), squirreltail (Sitanion hystrix), timothy (Phleum spp.), poa (Poa spp.), spike (Trisetum spicatum), Indian ricegrass (Oryzopsis hymenoides), and some sedges (Cyperaceae spp.). Principle annual grass species is cheatgrass (Bromus tectorum). Principal forb species include: yarrow (Achillea millefolium), dandelion (Taraxacum officinale), Richardson's geranium (Geranium richardsonii), penstemon (Penstemon spp.), mulesears (Wyethia amplexicaulis), golden aster (Chrysopsis villosa), arrowleaf balsamroot (Balsamorhiza sagittata), hawkbit (Agoseris pumila), larkspur (Delphinium spp.), and scarlet gilia (Gilia pulchella). Primary associated shrub species include: sagebrush (Artemesia spp.), shadscale (Atriplex confertifolia), greasewood (Sarcobatus spp.), creosote (Larrea tridentate), rabbit brush (Crysothamnus spp.), cinquefoil (Potentilla simplex), snowberry (Symphoricarpos albus), and elderberry (Sambucus spp.). Primary associated tree species is juniper (Juniperus spp.)."

> "Shrublands at 670-3,150 m (2,200-10,300 ft) elevation principally dominated by greasewood (Sarcobatus vermiculatus), shadscale, graymolly (Kochia vestita), mat-atriplex (Atriplex corrugata), Castle Valley clover (Atriplex cuneata), winterfat, budsage (Artemisia spinescens), four-wing saltbush (Atriplex canescens), halogeton (Halogeton glomeratus), Mormon tea (Ephedra spp.), horsebrush (Tetradymia canescens), snakeweed and rabbitbrush; or low elevation perennial grassland co-dominate with shrubland. Principal grassland species include: galleta, Indian ricegrass, three-awn grass (Aristida glauca) and sand dropseed. Primary associated forb species include: desert trumpet (Eriogonum inflatum). Primary associated shrub species include: sagebrush, and black brush (Coleogyne ramosissima); other associated species include seepweed (Suaeda torreyana)."

Based on the report by Lupis et al. (2007) we agree that the habitat that will be created at the Mill site following revegetation will include species consistent with prairie dog occupation.

Table D.37 presents an updated assessment of maximum burrow depths for animal species that may occur on the Mill site. Based on a review of literature for burrow depths, the species that have the potential for the deepest burrows are badger (228 cm), northern pocket gopher (150 cm), and Gunnison prairie dog (427 cm). As discussed above, both the badger and Gunnison prairie dog were observed during the 2012 animal survey, while there is no evidence that the northern pocket gopher occurs in the vicinity of the Mill site from both the 1978 and 2012 surveys.

The proposed cover system is a monolithic evapotranspiration (ET) cover that consists of the following layers from top to bottom: 15 cm of a topsoil-gravel erosion protection layer over 107 cm of a water storage, biointrusion and radon attenuation layer over 75 cm of a highly compacted radon attenuation layer over 75 cm of a grading and radon attenuation layer. The proposed cover system does not contain a biobarrier (e.g. cobble layer) to minimize potential intrusion by burrowing animals. The proposed cover system is designed to minimize burrowing animal intrusion through the use of thick layers of soil cover in combination with a highly compacted layer placed at a depth that is below the expected burrowing depths among species that may inhabit the site. The thickness of the cover (total of 272 cm), the use of a highly compacted radon attenuation layer located at a depth between 122 and 197 cm, and a final 75 cm layer below the compacted zone will all contribute to minimizing any biointrusion through the cover. Considering the animal species that may inhabit the tailings cells and the thickness and physical nature of the cover, it is not anticipated that burrowing will extend below 122 cm or into the very top portion of the highly compacted zone. Burrowing into the highly compacted radon attenuation layer that begins at a depth of 122 cm will be restricted because of the high density of this material (95 percent Standard Proctor).

Table D.37. Range of maximum burrow depths for wildlife that inhabit or may inhabit the Mill site during the required performance period of at least 200 years

Species	Maximum Depth (cm)	Source
Pocket mouse	52 to 62 35-153	Kenagy 1973; Scheriber 1978

D.6 SOIL REQUIREMENTS FOR SUSTAINABLE PLANT GROWTH

There are two key components to establishing an ET cover with a sustainable plant community. The first is to select long-lived species that are adapted to the environmental conditions of the site. The second is to provide a cover soil that will function as an effective plant growth medium over the long term by supplying plants with adequate amounts of water, nutrients and rooting volume.

There are a number of soil characteristics that are particularly important to achieve long-term sustainability in semi-arid environments and include the following: pH, electrical conductivity (EC), sodium levels, percent organic matter, texture, bulk density, cation exchange capacity, macronutrient concentrations, available water holding capacity, and soil microorganisms. Table D.38 presents levels for most of these soil properties that are considered necessary for long-term sustained plant growth. In addition, the table includes soil property levels from soil samples of potential cover soil collected from stock piles at the Mill site in May 2009.

The soil properties of the potential cover soil that are acceptable for sustaining long-term plant growth include: pH, EC, sodium adsorption ratio (SAR), percent clay content, and extractable phosphorus. Those soil properties that appear to be deficient and would need improvement include: percent organic matter, total nitrogen, and extractable potassium.

Cation exchange capacity was not measured in the potential cover soil, but it is believed that the cover soil will have an acceptable level for sustained plant growth based on the percent clay content and a recommendation that an organic matter amendment be added to the soil during the reclamation process. Bulk density of the emplaced cover material will be specified in the cover design and will be controlled during the construction process to be within the sustainability range shown in Table D.38.

Table D-38. Soil Properties and Their Range of Values Important for Sustainable Plant Growth, Along with Analytical Results of Soil Available for ET Cover Construction at the Mill Site

Soil Property	Level for Sustainability	Reference	Levels for On-Site Soil
pH (units)	6.6 to 8.4	Munshower (1994)	7.7 to 8.1
EC (mmhos/cm)	≤4.0	Munshower (1994)	<1.5
Sodium adsorption ratio	≤12	Munshower (1994)	<0.5
Organic matter (%)	1.0 to 3.0	Smith et al. (1987)	0 to 0.4
Texture (%)	> 50% silt and clay	Brady (1974)	> 50% silt and clay
Bulk density (g/cm^3)	1.2 to 1.8	Brady (1974)	1.59 to 1.99†
Water holding capacity (cm H_2O/cm soil)	0.08 to 0.16	Brady (1974)	0.084-0.14†
Cation exchange capacity (meq/100g)	5 to 30	Munshower (1994)	Not measured
Total nitrogen (%)	0.05 to 0.5	Harding (1954)	0.02 to 0.05
Extractable phosphorus (mg/kg)	6 to 11	Ludwick and Rogers (1976)	10 to 57
Extractable potassium (mg/kg)	60 to 120	Ludwick and Rogers (1976)	11 to 36

†Calculated values

In order for the potential cover soil to function as a normal soil and provide long-term sustainable support for the vegetation component of the ET cover, it will be amended to improve organic matter content, nitrogen and potassium levels. An organic matter amendment will also improve available water holding capacity and cation exchange capacity. The proposed organic amendment is composted biosolids. Composted biosolids have been successfully used in mined land reclamation over the past 40 years. This amendment would also provide a source of soil microorganisms that will function to cycle nutrients over time and ensure sustainable plant growth. Composted biosolids would be applied at a rate of 10 tons/acre and incorporated into the upper six inches of the water storage layer of the cover system. Composted biosolids are also a source of nitrogen, phosphorous and potassium and will serve to improve organic matter content and soil fertility. The following discussion provides the rationale for selecting composted biosolids as the amendment of choice for the cover soil.

Type of Amendment, Application Rates, and Costs – There are three possible soil amendments that would be a source of organic matter and nutrients for sustained plant growth. These amendments include composted biosolids, a combination of manure and hay, or a commercial organic fertilizer such as Biosol®. Biosol® is a highly effective organic amendment but would be cost prohibitive if the objective is to achieve 1 percent organic matter content in the soil. It would require the addition of at least 10 tons/acre to meet this organic matter target and the cost would be approximately $12,300/acre, which includes a product cost of $12,000/acre, transportation cost of $100/acre, and an application cost of $200/acre. Composted biosolids would be equally effective as Biosol®, but much less expensive. Composting of biosolids is a proven method for pathogen reduction and results in a product that is easy to handle, store, and use. The end product is usually a Class A, humus-like material without detectable levels of pathogens that can be applied as a soil amendment. Composted biosolids provide large quantities of organic matter and nutrients (such as nitrogen and phosphorus) to the soil, improves soil texture, and elevates soil exchange capacity. If composted biosolids were obtained from Farmington, NM (which appears at this time to be the closest source), the cost for a 10 ton/acre application rate would be $1,530/acre, which includes $260/acre for product cost, $1,070/acre for transportation, and $200/acre for application. The use of manure and hay would be the least effective amendment because both products have the potential of adding unwanted weed seed to the cover vegetation and manure is relatively high in nitrogen and if not properly off set with hay, there is a potential of having excessive nitrogen introduced into the cover system that would also lead to a proliferation of unwanted weeds.

Method of Application – Composted biosolids are produced by mixing biosolids (treated sewage sludge) and wood waste material. Composted biosolids are easy to apply and would be broadcast over the soil surface using a commercial manure spreader and the amendment would then be incorporated with a chisel plow or disc plow.

Limitations of Soil Amendments – Composted biosolids have few limitations as a soil amendment. Composted biosolids are often low in readily available nitrogen, but have high organic nitrogen levels that can be slowly released for plant use over time. The EPA has established rules for the land application of biosolids that address concerns about possible pathogen transmittal, nitrate pollution, and trace metal contamination (EPA, 1993 and 1995). In order to be land applied, a particular biosolid must have undergone a pathogen reduction process, must contain less than a specified amount of bacterial pathogens, and must meet limits for heavy metal concentration.

Considerable research has been conducted over the past 40 years on the interactions between biosolids, soil properties, plant growth and environmental quality. Amendment of disturbed soils with composted biosolids has been shown to increase soil organic matter, cation exchange capacity, soil nutrient levels, microbial biomass and activity, water holding capacity, and aggregate stability, and also to reduce soil bulk density and metal availability for plant uptake. The potential for successful reclamation with composted biosolids is tremendous and most of the highly beneficial properties of composted biosolids as a soil amendment come from its high organic matter content (Sopper, 1993). The use of composted biosolids is extremely important where topsoil is inadequate in amount or quality (Sopper, 1993; Munshower, 1994).

The application of composted biosolids on disturbed land generally has had a very beneficial effect on the establishment and growth of grasses and forbs (Sopper, 1993; Haering et al., 2000). It facilitates rapid establishment and vigorous growth of herbaceous plants. Sites treated with composted biosolids generally have a greater percent cover, greater aboveground production, and better developed root systems compared to non-amended sites or sites treated with just inorganic fertilizers (Sopper, 1993; Haering et al., 2000). The use of composted biosolids also aids in the establishment and growth of shrubs. Annual height and diameter growth is improved with composted biosolids and overall woody plant survival is increased if competition from herbaceous plants is not an issue (Sopper, 1993; Haering et al., 2000).

Field studies at the Climax Molybdenum Mine near Leadville, Colorado conducted by Carlson et al. (2006) examined the effect of composted biosolids on tailings reclamation over a seven-year period. The findings of this study were that composted biosolids are an effective means of establishing soil microbe and vegetation communities on tailings. The authors concluded that: over seven years and in extreme growing conditions, biosolid amendments reduced soil toxicity [by immobilizing heavy metals], neutralized acidity, and introduced constituents [e.g. nutrients and soil microbes] necessary to sustain vegetation communities on tailings capped with overburden material.

In a very long-term study conducted by Paschke et al. (2005) the effect of biosolids amendments were assessed on disturbances in a sagebrush community in northwestern Colorado. The authors reported that 24 years after biosolids were applied on fertile and infertile soil material that: "… biosolids amendments have long-lasting effects on soil fertility and plant community composition…"

The greatest limitation for the use of composted biosolids at the Mill site will be availability of the product. Availability varies over time depending upon supply and demand. Since the Mill site is in a remote location, sources of composted biosolids in the quantities needed for tailing cell reclamation are limited and advanced planning will be required to secure the quantities needed when the cover system is being constructed.

D.7 WEED MANAGEMENT

Weed management would be conducted on the Mill site by identifying the presence of any noxious weeds during annual vegetation surveys and developing a weed control plan that is specific to the species that are present (Table D.39). Noxious weed control is species dependent and both method and timing will vary from species to species.

Each survey will identify noxious weed populations and locate these populations on a map using a set of symbols to identify species, size of the infestation, and density of the population. The effectiveness of control methods will also be documented in each annual survey. In addition, immediately adjacent off-site properties will be visually surveyed to a distance of 100 feet. Inspections will be conducted by personnel familiar with the identification of noxious weeds in the area and based on Utah's Noxious Weed List.

The selected control methods will be based on the type, size, and location of the mapped noxious weeds. The treated area(s) will be monitored and re-inspected annually for new weed introductions and to evaluate the success of the control methods. Prevention is the highest priority weed management practice on non-infested lands; therefore protecting weed-free plant communities is the most economical and efficient land management practice. Prevention is best accomplished by ensuring that new weed species seed or vegetative reproductive plant parts of weeds are not introduced into new areas, and by early detection of any new weed species before they begin to spread.

Control methods may include chemical or mechanical approaches. The optimum method or methods for weed management will vary depending on a number of site-specific variables such as associated vegetation, weed type, stage of growth, and severity of the weed infestation.

Table D.39. Noxious Weed Species

Scientific Name	Common Name
Utah State—Listed Noxious Weeds	
Acroptilon repens	Russian knapweed
Cardaria spp.	Whitetop (all species)
Carduus nutans	Musk thistle
Centaurea diffusa	Diffuse knapweed
Centaurea solstitialis	Yellow star thistle
Centaurea stoebe ssp. micranthos	Spotted knapweed
Centaurea virgate ssp. Squarrosa	Squarrose knapweed
Cirsium arvense	Canada thistle
Convolvulus spp.	Bindweed (all species)
Cynodon dactylon	Bermuda grass
Elymus repens	Quackgrass
Euphorbia esula	Leafy spurge
Isatis tinctoria	Dyer's woad
Lepidium latifolium	Broadleaf pepperweed
Lythrum salicaria	Purple loosestrife
Onopordum acanthium	Scotch thistle
Sorghum almum	Perennial sorghum (all species)
Taeniatherum caput-medusae	Medusahead
San Juan County—Listed Noxious Weeds	
Aegilops cylindrical	Jointed goatgrass
Alhagi maurorum	Camelthorn
Asclepias subverticillata	Western whorled milkweed
Solanum elaeegnifolium	Silverleaf nightshade
Solanum rostratum	Buffalobur

<u>Chemical Control</u>
Chemical control consists mostly of selective and non-selective herbicides. Considerations for chemical controls include: herbicide selection, timing of application, target weed, desirable plant species being grown or that will be planted, number of applications per year and number of years a particular species will need to be treated for desired control. Also important are the health and safety factors involved, and the need to consider undesirable impacts. The use of herbicides will be in compliance with all Federal and State laws on proper use, storage, and disposal. The chemical application will be done by a licensed contractor in accordance with all applicable laws and regulations and all label instructions will be strictly followed. Applications of herbicides would

not be permitted when the instructions on the herbicide label indicate conditions that are not optimal.

Mechanical Control

Mechanical control is the physical removal of weeds from the soil and includes tilling, mowing, and pulling undesirable plant species. Tillage is most effective prior to seeding and establishment of desirable vegetation. The tillage method of weed control can be effective in eliminating noxious perennial weeds when repeated at short intervals (every 1-2 weeks) throughout the growing season. Tillage has the drawback of indiscriminately impacting all vegetation interspersed with weeds in established areas and can eliminate competitive, desirable vegetation leaving behind a prime seedbed for weeds to reinvade. Mowing can be an effective method for controlling the spread of an infestation and preventing the formation and dispersal of seeds. Mowing is most effective on weeds which spread solely or primarily by seed. In order to achieve this, it must be repeated at least twice during the growing season prior to, or shortly after bloom. Also, even the most intense mowing treatment will not kill hardy perennial weeds. Additional considerations will be made when selecting control treatments when specific situations arise regarding type, size, and location of weed infestations. Examples of this are perennial versus biennial, broadleaf versus grasses, noxious weeds interspersed with desirable vegetation, large monoculture patches, or small patches requiring spot treatment.

Treatment windows schedules, based on the control methods chosen and the noxious weeds present, will be established for each treatment area. The best time to treat perennial noxious weeds is in the spring or fall during their active growth phase. Different species will have different optimum treatment times even with the same type of control. Perennial weeds usually grow vegetatively in the spring, flower and seed in late spring and early summer, enter dormancy during the summer and actively grow again in the fall. The treatment windows selected will depend on the species present and control methods selected.

The final preparatory step is to determine the priority for areas to be treated. Prioritization ensures that the most important areas are dealt with at the most effective times. Important areas of concern include areas that may transport weed seeds. These areas include ditches, roadsides, and land equipment storage sites. Large monoculture patches are of concern wherever they occur and would always be high priority. Also, small patches of weeds would be treated to prevent expansion of weed populations.

Once the treatment plan is implemented, detailed records will be kept, and success or failure of treatment will be recorded so as to eliminate unsuccessful treatments.

D.8 REVEGETATION ACCEPTANCE GOALS/CRITERIA AND MONITORING

The following Revegetation Acceptance Goals/Criteria have been adapted from the Monticello Site and would be used at the Mill site to determine reclamation success.

Criterion 1 Species Composition

a. The vegetative cover (the percentage of ground surface covered by live plants) shall be composed of a minimum of five perennial grass species (at least four listed as native), one perennial forb and two shrub species listed in Table D.1.

Criterion 2 Vegetative Cover

a. Attain a minimum vegetative cover percentages of 40 percent.

b. Individual grass and forb species listed in Table D.1 that are used to achieve the cover criteria shall have a minimum relative cover (the cover of a plant species expressed as a percentage of total vegetative cover) of 4 percent and a maximum relative cover of 40 percent.

c. Individual species not listed in Table D.1 may be accepted as part of the cover criteria if it is demonstrated that the species is native or adapted to the area and is a desirable component of the reclaimed project site.

d. Species not listed in Table D.1, including annual weeds or other undesirable species shall not count toward the minimum vegetative cover requirement. Every attempt should be made to minimize establishment of all non-noxious weeds.

e. Reclaimed areas shall be free of state- and county-listed noxious weeds (Table D.40).

f. The vegetative cover shall be self-regenerating and permanent. Self-regeneration shall be demonstrated by evidence of reproduction, such as tillers and seed production.

Criterion 3 Shrub Density

a. A minimum shrub density of 500 stems per acre

b. Shrubs shall be healthy and have survived at least two complete growing seasons before being evaluated against success criteria

Monitoring

Plant cover would be measured annually on the tailing cells for a minimum of ten years or until the revegetation goals stated above are achieved. Cover would be measured by the point method, using a vegetation sighting scope mounted on an adjustable tripod with a level (or similar instrument). Cover would be measured for each species encountered, as well as litter, rock, and bareground. Cover measurements would be made along a minimum of ten randomly placed transects on each tailing cell that are 100 feet long. A total of 100 points would be sited at one-foot intervals along each transect to collect cover data in the categories of live vegetation, litter, rock, and bareground. Sample adequacy would be determined for each tailing cell using the following formula that identifies the minimum number of samples that are necessary to estimate the population mean at a 90 percent level of confidence. Total live vegetation cover would be used to calculate sample adequacy.

$$n = \frac{t^2 s^2}{(.10x)^2}$$

Where: n = minimum number of samples required to meet sample

adequacy requirements
s^2 = variance
t^2 = 1.64 for 90% confidence
x = sample mean

Shrub density would be measured in belt transects placed on either side of the cover transects. All shrubs would be counted within a three-foot wide strip or belt transect along each side of the transect used for point cover measurements, resulting in a belt transect that is six-feet wide and 100 feet long.

In addition to the above cover sampling, annual observations would be made of overall plant community health and sustainability. Overall health would be based on plant vigor, presence of annual weeds, and signs of plant deficiencies or toxicities. Plant community sustainability would be based on observations of reproduction, including both vegetative reproduction, such as tillering, and seed production.

If revegetated areas are not making satisfactory progress in meeting revegetation goals outlined above, then remedial actions will be implemented as needed. These actions may include fertilization/soil amendments, reseeding, weed control, and/or erosion control depending upon the cause of the problem that may exist and the best remediation approach to ensure plant community success. Potential revegetation problems that are most likely to occur based on typical revegetation projects in the semiarid west and on experiences at the Monticello Site fall into two categories. The first is poor initial plant establishment following revegetation practices and the second is poor plant growth during post-revegetation management. Poor initial plant establishment can be caused by a number of factors including unfavorable soil conditions related to texture or soil chemistry, improper seedbed preparation, improper seeding techniques, improper species selection, poor seed quality, planting in the wrong season, seed predation, and inadequate precipitation. If revegetation at the Mill site results in unacceptable initial plant establishment, the cause of this response will be investigated, the identified cause will be corrected, and the necessary revegetation practices will be applied until successful plant establishment has occurred. The most likely cause of poor initial plant establishment at the Mill site would be low precipitation and additional seedings would be required in a subsequent year(s) until precipitation improves and an adequate stand of vegetation is achieved. Additional mulching to control erosion and improve soil moisture conditions for seed germination and initial seedling growth would be part of the remedial process. Poor plant growth during post-revegetation management has been an issue at the Monticello Site as it relates to shrub establishment. The primary species that has been an issue is big sagebrush and the cause of the problem has been seedling damage associated with vole herbivory.

D.9 SUSTAINABILITY OF THE COVER DESIGN

D.9.1 CLIMATE CHANGE

Climate, more than any other factor, controls the broadscale distributions of plant species and vegetation. At finer scales, other factors such as local environmental conditions including soil nutrient status, pH, water-holding capacity and the physical elements of aspect or slope influence the potential presence or absence of a species. However, intra- and inter-specific interactions, such as competition for resources (light, water, nutrients), ultimately determine whether an individual plant is actually found at any particular location (Sykes 2009). Rapid climate change associated with increasing greenhouse gas emissions (IPCC 2007) influences current and future vegetation patterns. Other human-influenced factors are, however, also involved. Sala et al. (1997) identified five different drivers of change that can be expected to affect global biodiversity over the next 100 years. Globally, land use change was considered the most important driver of change, followed by climate change, airborne nitrogen deposition, biotic interactions (invasive species) and direct CO_2 fertilizing or water use efficiency effects.

Predicted changes in climate that may occur in the southwestern U.S. include increased atmospheric concentrations of CO_2, increased surface temperatures, changes in the amount, seasonality, and distribution of precipitation, more frequent climatic extremes, and a greater variability in climate patterns. Recent temperature increases have made the current drought in the region more severe than the natural droughts of the last several centuries. This drought has caused substantial die-off of pinyon pine trees in approximately 4,600 square miles of pinyon-juniper woodland in the Four Corners region (Breshears et al. 2005). Williams et al. (2010) examined correlations between climate and the radial growth of trees across North America. They show that conifer trees in the southwest are particularly sensitive to temperature and aridity relative to other regions. They used climate-tree growth relations calculated for the past 100 years, combined with Intergovernmental Panel on Climate Change (IPCC) climate model estimates for the 21st century to predict the likely fate of important southwest tree species such as pinyon pine. They concluded that woodlands and forests will experience substantially reduced growth rates and increase mortality at many southwest sites as the century progresses.

The specific physiological effects of increasing GHG emissions (particularly CO_2) on vegetation include increased net photosynthesis, reduced photorespiration, changes in dark respiration, and reduced stomatal conductance which decreases transpiration and increases water use efficiency (Patterson and Flint 1990). Ambient temperature affects plants directly and indirectly at each stage of their life cycle (Morison and Lawlor 1999). Water (i.e. soil moisture) is usually the abiotic factor most limiting to vegetation, especially in arid and semi-arid regions. Carbon dioxide, temperature, and soil moisture effects on plant physiology are exhibited at the whole-plant level in terms of growth and resource acquisition. In addition to the individual effects of increasing temperatures, CO_2 is the additional interactive effect on photosynthetic productivity and ecosystem-level process (Long and Hutchin 1991).

Plants are finely tuned to the seasonality of their environment, and shifts in the timing of plant activity (i.e. phenology) provide some of the most compelling evidence that species and ecosystems are being influenced by global environmental change (Cleland et al. 2007). Changes in the phenology of plants have been noted in recent decades in regions around the world (Bradley et al. 1999; Fitter and Fitter 2002; Walther et al. 2002; Parmesan and Yohe 2003). Phenology of plant species is important both at the individual and population levels. Specific timing is crucial to optimal seed set for individuals and populations; and variation among species in their phenology is an important mechanism for maintaining species coexistence in diverse plant communities by reducing competition for pollinators and other resources. Global climate change could significantly alter plant phenology because temperature influences the timing of development, both alone and through interactions with other cues, such as photoperiod.

Shifts in the relative competitive ability of plants that experience changes in CO_2, surface temperatures, or soil moisture may result in changes to their spatial distribution (Long and Hutchin 1991; Neilson and Marks 1994). Increases in temperature may enhance the competitive ability of C_4 plants (such as grasses) relative to C_3 plants (shrubs and trees) (Owensby et al. 1999), especially where soil moisture (Neilson 1993) or temperature (Esser 1992) is limiting.

There are numerous uncertainties and complexities associated with the use of all regional climate models with regard to their ability to reliably forecast longer-term future climate conditions in the North American South West (NASW) and at the Mill site. Therefore, attempts to extend the results from climate model predictions forecasting climate conditions through the end of the 21st century to timeframes of 200 to 1,000 years will likely result in further compounding of these uncertainties and result in unreliable predictions. We identified this concern in earlier discussions presented on the topic of climate change.

We have reviewed references cited in the Division's Rd 1 Interrogatories for White Mesa Revised ICTM Report on estimating the range of future climates (CNRWA 2005; NRC 2003; NRC 1997). The Center for Nuclear Waste Regulatory Analyses (CNRWA 2005) conducted an analysis of factors contributing to uncertainty in estimating future climates at Yucca Mountain. Their report concludes the following:

> "In summary, research performed within the last five years suggests that the timing of climate changes over the next 100,000 years may be difficult to infer from the patterns of climate change over the last 500,000 years due to the unusually low eccentricity of Earth's orbit and, possibly, the influence of anthropogenic greenhouses gases. After 100,000 years, the Earth's orbital climate forcing will be stronger, and the influence of greenhouse gases may have diminished so that the Pleistocene climate history may offer a better analog in terms of timing of climate changes. In terms of the characteristics of future climates (i.e., mean annual precipitation and temperature, seasonal weather patterns, and storm intensities), the characteristics inferred from paleoclimate reconstructions and present day analog records may represent the range of climate conditions that will occur in the future, even if the timing of these climates cannot be reliably estimated. The greatest uncertainty in future climate conditions relates to anthropogenic effects that may result in climates in southern Nevada that do not have analogs with present or Pleistocene climates, such as prolonged El Niño conditions. The nature, likelihood, and duration of such nonrepresentative climate conditions cannot be reliably assessed based on current research. Over longer time periods, the range of conditions inferred from the Pleistocene paleoclimate record reasonably bounds future climate during the period of geologic stability."

We agree with NRC's preferred approach of using paleoclimate data to estimate the likely range of future conditions. In fact, in our previous discussion of climate change in Attachment G (EFRI, 2012), we discussed the paleoclimate approach presented by Waugh and Petersen (1994) for the Monticello site.

Waugh and Petersen (1994) summarize future climate change as follows:

> "Global mean temperature may increase by 1.8 to 5.2^{o}C in the next century, in response to an industrial age buildup of carbon dioxide (CO_2), methane, and other gases (Houghton et al. 1992). Model projections of the magnitude of warming vary, depending on whether factors such as CO_2 fertilization, feedback from stratospheric ozone depletion, and the radiative effects of sulfate aerosols are taken into account. Model projections of precipitation responses to greenhouse warming also are inconsistent (Houghton et al. 1990; Crowley and North 1991; Washington and Meehl 1984; Wilson and Mitchell 1987; Schlesinger and Mitchell 1987). Some regions may be effectively wetter and others drier, depending on the balance of the greater potential evaporation and the greater water-holding capacity of a warmer atmosphere. Greenhouse warming may eventually be overwhelmed as the earth plunges into another ice age. Models of cyclic astronomical

> forcing of climate agree that, without anthropogenic disturbances, a long-term cooling trend that started about 6,000 years ago will continue, climaxing with a major glaciation in about 60,000 years (Imbrie and Imbrie 1980; Berger et al. 1991). In contrast, aperiodicity in the timing of past ice ages is evident in oxygen isotope records (Winograd et al. 1992). Other paleorecords suggest that certain feedback mechanisms have caused rapid and unpredictable transitions into ice ages (Berger and Labeyrie 1987; Phillips et al. 1990)."

Waugh and Petersen (1994) concluded from their investigation that despite uncertainty about drivers of future climate change, climate extremes in the next 1,000 years likely will not exceed those associated with the last glacial and interglacial periods. Therefore, paleo-records of full glacial and Altithermal climates in the Four Corners region provide reasonable ranges of possible future climate and should be incorporated in assessments of the long-term performance of tailings disposal facilities. For Monticello, Utah, full glacial and Altithermal climate reconstructions provide working levels of 2 to 10^{o} C mean annual temperature and 38 to 80 cm mean annual precipitation. If we assume that a similar range of temperature and precipitation could also occur at the Mill site, then during the next glacial phase anticipated to occur approximately 60,000 years into the future the climate would be a colder and wetter compared to current conditions, and if conditions post-glaciation result in a warm period the climate would be warmer and wetter than current conditions.

Table D.41 presents a list of possible climate scenarios for the Mill site, their likelihood of occurrence and the resulting plant community type that would develop during the required performance period. From the review of climate change literature applicable to the southwest U.S. and an analysis of the impact of various climate change scenarios, it is our conclusion that the most likely plant community type that will be maintained throughout the 200- to 1,000-year performance period is a community dominated initially by cool season grasses, with a long-term transition to dominance by warm season grasses and shrubs as atmospheric CO_2 and temperature continues to increase and precipitation ether increases or decreases.

D.7.2 Plant Community Succession and Potential for Species Colonization

Plant succession is the ecological process of directional vegetation change over time, usually beginning with relatively-short lived herbaceous plants and culminating in plant communities dominated by long-lived, generally woody species. Succession occurs on all sites. The rate of succession can be relatively rapid, especially in regions of higher rainfall, or it can be very slow, as in some desert and arctic regions, but this process of vegetation change is constantly taking place.

Two common aspects of succession are 1) an increase in vegetation structure and 2) an increase in the relative amounts of woody plants. Both of these aspects have profound implications to the function of cover systems. Vegetation structure refers to the shape of the vegetation, e.g., height, coverage, and stratification. Structure increases as succession proceeds, both above- and belowground. Aboveground, the height of the vegetation increases (e.g., grasses may be replaced by shrubs), coverage of the soil surface increases, and layering (strata) of vegetation occurs, with different species occupying different vertical layers. Similar processes occur belowground. Root systems become deeper as shallow-rooted species are replaced by deeper-rooted species, root biomass increases in lower soil depths as the number and types of species increase, and the density of the root system increases in the various layers.

Table D.40. Possible Climate Scenarios for the Mill Site, Likelihood of Occurrence and Projected Change in Plant Species Composition Compared to the Initial Grass/forb Community Established on the Soil Cover

Possible Climate Scenarios	Likelihood of Occurence[9]	Projected Plant Community Type in 1,000 Years with Seeded Grass/Forb as the Initial Community
Warmer and Dryer than Present[1]	Highly Likely	Grass/forb community with an increase in warm season species.
Warmer and Wetter than Present[2]	Highly Likely	Will depend on distribution of additional precipitation. If more precipitation in winter months, then the plant community would experience an increase in woody plants; if more precipitation in the summer months, then the plant community would continue as a grass/forb type.
Warmer than Present with Similar Total Precipitation[3]	Unlikely	Grass/forb community with an increase in warm season species.
Cooler and Wetter than Present[4]	Highly Unlikely	Shift to more woody plants because of more snow in winter months.
Cooler and Dryer than Present[5]	Highly Unlikely	Shift to more woody plants because of more snow in winter months.
Cooler than Present with Similar Precipitation[6]	Highly Unlikely	Shift to more woody plants because of more snow in winter months.
Dryer than Present with Similar Temperature[7]	Unlikely	Grass/forb community with an increase in warm season species because of less overall moisture and increase in atmospheric CO_2.
Wetter than Present with Similar Temperature[8]	Unlikely	Shift to more woody plants because of more winter precipitation.

[1]Results in less total precipitation but shift to less snow and more rain in winter months.
[2]Results in more total precipitation with shift to less snow and more rain in winter months or more rain in summer months.
[3]Results in no change in total precipitation but shift to less snow and more rain in winter months.
[4]Results in more total precipitation with shift to more snow in winter months.
[5]Results in less total precipitation but shift to more snow in winter months
[6]Results in no change in total precipitation but shift to more snow in winter months.
[7]Results in less total precipitation.
[8]Results in more total precipitation.
[9]Likelihood of occurrence based on majority of climate model estimates analyzed by Cayan et al. 2010 and Seager and Vecchi 2010, with a focus on the southwest U.S.

As the vegetation shifts from dominance by herbaceous plants (e.g., grasses), which have relatively shallow root systems but with very dense root mass in the upper profile, to dominance by woody species (e.g., shrubs), which have deeper roots systems with proportionately more roots in deeper layers, the hydrological dynamics of the system change. Early successional plant communities tend to extract most of the water they transpire from the upper soil profile. Late successional communities have greater ability to extract water from depth. This can be both a positive and a negative in the functional efficiency of covers. Because of successional changes in the vegetation, the plant-soil-water characteristics of a cover are likely to become very different over time. Conditions 200 years or more after construction are not likely to be similar to those soon after construction was completed. In some ways, conditions will be more favorable, e.g., evapotranspiration will likely be higher thus reducing the amount of deep infiltration and stability of the vegetation may be greater. In other ways, conditions will be less favorable, e.g., deeper root systems increase the concern for biointrusion. Because succession is a process that is near-universal ecologically, these changes have been accounted for in the cover design.

As stated earlier, the proposed cover system is a monolithic ET cover that consists of the following layers from top to bottom: 15 cm of a topsoil-gravel erosion protection layer over 107 cm of a water storage, biointrusion and radon attenuation layer over up to 110 to 136 cm of a highly compacted radon attenuation layer over 76 cm of a grading and radon attenuation layer. The proposed cover system does not contain a biobarrier (e.g. cobble layer) to minimize potential intrusion by plant roots during the required performance period. The proposed cover system is designed to minimize plant root intrusion through the use of thick layers of soil cover in combination with a highly compacted layer placed deep within the cover. The climax community for the Mill site is believed to be Big Sagebrush based on the current community type at the site and the relatively deep fine loamy soils that are present. If climate trends towards a warmer and dryer climate for the White Mesa area over the next 200 to 1,000 years, it is unlikely that sagebrush will remain on site and a community dominated by warm season species and more arid shrub species (e.g. shadscale saltbush, blackbrush and Mormon tea) may occur.

As discussed above, the process of succession and the effect of climate change will bring about changes in species composition in the tailings cover system. Our best forecast for the percentage of potential species colonization would be for a small percent of non-seeded species establishing during the first 50 years. The seeded community will be highly sustainable and big sagebrush would be the primary invader into the cover system. It is estimated that the established community will consist of 60 to 70 percent seeded species and 30 to 40 percent non-seeded species at end of the first 100 years. These non-seeded species will include big sagebrush and broom snakeweed, and a few grass and forb species common in the area. During the next 100 years the plant community will begin to transition to warm season species and big sagebrush will begin to diminish. By the end of the second 100 years it is estimated that the plant community will consist of 30 to 40 percent seeded and 60 to 70 percent non-seeded species and many of the non-seeded species will be warm season grasses and more arid shrub species. This trend will most likely continue through the remainder of the performance period with only 10 to 20 percent of the original seeded species still present and these would include blue grama and galleta. The remainder of the community would consist of more warm season grasses and shrubs that will have migrated north and higher in elevation with the warming climate.

APPENDIX E

SLOPE STABILITY ANALYSIS

E.1 INTRODUCTION

This appendix presents the methods, input and results of slope stability analyses of the tailings cells at the Energy Fuels Resources (USA) Inc. (EFRI) White Mesa Uranium Mill (Mill). The Mill is located approximately 6.0 miles south of Blanding, Utah. These analyses were conducted according to applicable stability criteria under static and seismic conditions, including geotechnical stability criteria in NRC (2003). These analyses are an update to the slope stability analyses presented in MWH (2011) to incorporate revisions to the analyses to address State of Utah, Division of Waste Management and Radiation Control (DWMRC) (formerly Utah Division of Radiation Control, DRC) interrogatories (DRC, 2012) and review comments on EFRI responses to 2012 interrogatories (DRC, 2013). These analyses also incorporate the revised cover grading design, results of cover material testing conducted in 2010 and 2012 (summarized in Attachment B of EFRI, 2012), and the results of tailings testing conducted in 2013 (presented in MWH, 2015b).

Slope stability analyses were performed using limit equilibrium methods with the aid of the computer program SLOPE/W (GEO-SLOPE, 2007). The SLOPE/W program calculates factors of safety by any of the following methods: (1) Ordinary Fellenius, (2) Bishop's Simplified, (3) Janbu's Simplified, (4) Spencer, (5) Morgenstern-Price, (6) U.S. Army Corps of Engineers, (7) Lowe-Karafiath, and (8) Generalized Limit Equilibrium. The Morgenstern-Price method (Morgenstern and Price, 1965) with a half-sine function for inter-slice forces was selected for performing the computations in SLOPE/W. The method uses both circular and non-circular shear surfaces and satisfies both moment and force equilibrium.

E.2 CRITICAL CONDITIONS AND GEOMETRY

Slope stability analyses are typically conducted for scenarios that represent the critical conditions for post-reclamation. For the White Mesa Mill tailings cells, critical conditions for post-reclamation were evaluated and included: (1) reclaimed outside surfaces of the embankment with a 5H:1V slope, (2) existing inside surfaces of the embankments with a 2H:1V slope, and (3) conservative shear strength parameters based on previous reports.

A critical cross section, cross section A, was selected through the southern dike of Cell 4A near the southeast corner of the impoundment. The cross section location was selected based on overall impoundment height as well as base topography and is similar to the location used for the slope stability analyses presented in Titan (1996). The location of cross section A is shown in Figure E.1. The tailings are planned to be dewatered prior to placement of the final portion of cover. The phreatic surface was estimated to be five feet above the liner system for the analyses.

A second cross section, cross section B, was selected through the northern embankment of the Cell 1 Disposal Area. This location was chosen to address DRC interrogatories (DRC, 2012). The location of cross section B is shown in Figure E.2. The material placed in the Cell 1 Disposal Area will include mill debris and contaminated soils. The embankment cross section was assumed to be fully drained and therefore a phreatic surface was not included in the analyses.

Slope stability analyses were performed by calculating factors of safety along circular and non-circular failure surfaces for both static and pseudo-static conditions. Circular failure surface analyses were conducted by targeting both shallow and deep failure surfaces. Block failure surfaces through the clay liner system were evaluated for cross section B. A number of failure surfaces were analyzed in order to calculate the factor of safety for the critical failure.

E.3 MATERIAL PROPERTIES

Material strength parameters used for the slope stability analysis are based on parameters presented in Denison (2009) for the Cell 4B slope stability analyses conducted by Geosyntec, historical laboratory testing on tailings and clay materials (Advanced Terra Testing, 1996; Chen and Associates, 1987; D'Appolonia, 1982; and Western Colorado Testing, 1999), laboratory testing conducted in 2010 and 2012 on potential cover borrow materials (see Attachment B of EFRI, 2012), laboratory testing conducted in 2013 on tailings (MWH, 2015b) and typical published values. The parameters for each material are discussed below and summarized in Table E.1.

Erosion Protection: The erosion protection materials include riprap and filter material on the embankment slopes, and rock mulch on the top surface of the cover system. Typical density values for sand and gravel were used for the riprap and filter materials. The riprap and filter material strength parameters were estimated based on the lower bound typical values from Lambe (1969) for loose to medium dense sand and gravel. The rock mulch consists of topsoil material mixed with 25 percent gravel by weight. The density of the rock mulch was based on the 2012 laboratory testing results for topsoil (see Attachment B of EFRI, 2012) and applying a rock correction based on 25 percent gravel by weight. The total unit weight of the rock mulch was calculated using the estimated dry density and the long-term water content presented in the radon analyses. Effective strength parameters of the rock mulch were estimated as an angle of internal friction of 33 degrees and no cohesion, based on a maximum plasticity index (PI) of the topsoil of 10 percent (listed in the specifications), and using the generalized relationship between PI and effective angle of internal friction presented in Holtz and Kovacs (1981).

Cover System: The cover system material properties were estimated based on the updated geotechnical site investigation in April 2012. The total unit weight values used in the model for the random fill layers were estimated using 2010 and 2012 laboratory tests conducted on potential cover borrow materials (see Appendix A.2) and based on the compaction effort for each layer. The total unit weights for the cover layers were calculated using the long-term water contents for the cover layers used in the radon analyses. Effective strength parameters for the cover materials were estimated based on the maximum measured PI (30) from the 2010 and 2012 laboratory test results and using the generalized relationship between PI and effective angle of internal friction presented in Holtz and Kovacs (1981), resulting in an angle of internal friction of 29 degrees and no cohesion.

Tailings Material: The dry density of the tailings was estimated as 96 pcf, based on laboratory tests (Chen and Associates, 1987 and Western Colorado Testing, 1999) and assuming the upper bound long-term density of the tailings should be no greater than 90 percent of the average laboratory measured maximum dry density for tailings. This is the same density used for the radon analyses. The total unit weight of the tailings was calculated using the long-term water content assumed for the tailings in the radon analyses. Based on existing operations at the site, the tailings deposits are primarily fine sands with silt and some clay. The strength parameters of the tailings were conservatively estimated using the Naval Design Manual for Soil Mechanics DM7-01 (NAVFAC, 1986) as zero percent relative density silty sand. The strength parameters used for the tailings (no cohesion and an effective angle internal friction of 25 degrees) are consistent with the values presented in Denison (2009) for the Cell 4B design stability analyses.

Contaminated Soils/Mill Debris: The materials to be placed in the Cell 1 Disposal Area include contaminated soils and mill debris. The contaminated soils will be from on-site and have similar properties as the cover soils. The material properties for the contaminated soils and mill debris were conservatively assumed to be the same as the cover soils (compacted to 85 percent standard Proctor compaction).

Clay Liner: Cell 1 will be lined with a clay liner. The dry density of the clay was estimated based on laboratory tests performed on Section 16 clay (D'Appolonia, 1982; Advanced Terra Testing, 1996) and assuming the clay will be compacted to 95 percent of standard Proctor compaction. The total unit weight for the clay was calculated using the estimated dry density and a long-term water content of 14 percent. The long-term water content was estimated based on 15 bar water contents measured for Section 16 clay samples by Chen and Associates (1987) presented in Titan (1996). The strength parameters for the clay were estimated using the average measured PI (60) of samples meeting the placement specifications for minimum PI and percent passing the No. 200 sieve, and the generalized relationship between PI and effective angle of internal friction presented in Holtz and Kovacs (1981), resulting in an angle of internal friction of 24 degrees and no cohesion.

Dike and Foundation: Density and strength parameters for the existing foundation and dike material were estimated as the values presented in stability analyses performed for the design of Cell 4B by Geosyntec (Denison, 2009). The strength parameters used in the model were based on laboratory testing results from samples obtained from the existing berm between Cell 4A and 4B (Denison, 2009).

Bedrock: Failures are not anticipated to occur within the bedrock underlying the embankment, due to the relatively high strength of the underlying sedimentary rock. Therefore, the material properties for the bedrock were modelled as those consistent with sedimentary rock.

Table E.1. Material Parameters Used in Model

Material	Total Unit Weight (pcf)	Effective Cohesion (psf)	Effective Friction Angle (deg.)
Riprap	125	0	36
Riprap Filter	125	0	30
Rock mulch	110	0	33
Cover Upper Layer (85% SP compaction)	107	0	29
Cover Middle Layer (95% SP compaction)	120	0	29
Cover Lower Layer (80% SP compaction)	100	0	29
Random Fill	100	0	29
Tailings	95	0	25
Contaminated Soils/Mill Debris	107	0	29
Clay Liner	110	0	24
Dike	137	900	26
Foundation	137	900	26
Bedrock	130	10000	45

E.4 SEISMIC ANALYSIS AND SEISMICITY

Stability analyses under seismic conditions were conducted as pseudo-static analyses, where a horizontal acceleration or seismic coefficient is applied to both cross-sections. This seismic coefficient represents the horizontal accelerations applied on the structure by an earthquake. A coefficient of 0.1 g was used for the analyses based on the site-specific probabilistic seismic hazard analysis (MWH, 2015a). This seismic coefficient represents the seismic loading for the Maximum Credible Earthquake (MCE) calculated to occur during the long-term life of the embankment. A summary of the site seismicity is provided in the MWH (2015a).

A liquefaction analysis was conducted for the tailings and is presented in Appendix F (revised version provided as Attachment G to this submittal). The results indicate the tailings are not susceptible to earthquake-induced liquefaction. For materials that do not liquefy or lose shear strength with seismic shaking, seismic slope stability is analyzed by a pseudo-static approach. This consists of application of an equivalent horizontal acceleration or seismic coefficient to the structure being analyzed. The seismic coefficient represents an inertial force due to strong ground motions during the design earthquake, and is represented as a fraction of the peak ground acceleration (PGA) at the site (typically at the base of the structure). The strategy of representing the seismic coefficient as a fraction of the PGA has been adopted in review of uranium tailings facility design and documented in DOE (1989). A seismic coefficient of 2/3 of the PGA typically represents the post-reclamation conditions. MWH (2015a) estimated the mean PGA for reclaimed conditions to be 0.15g. The seismic coefficient used for the pseudo-static stability analysis is 0.10g (equal to 2/3 of the PGA).

E.5 DISCUSSION OF STABILITY ANALYSIS RESULTS

The results of stability analyses for Cross-section A and B are presented in Table E.2. These values represent the lowest calculated factor of safety from a number of individual failure surfaces for a Morgenstern-Price Analysis.

Table E.2. Slope Stability Analysis Results

Cross-Section	Failure Type	Loading Condition	Required Factors of Safety	Calculated Factors of Safety
Cross Section A - Cell 4A Embankment	Shallow Circular	Static	1.5	3.05
		Pseudo-Static	1.1	1.99
	Deep Circular	Static	1.5	3.86
		Pseudo-Static	1.1	2.53
Cross Section B – Cell 1 Embankment	Shallow Circular	Static	1.5	2.64
		Pseudo-Static	1.1	1.71
	Deep Circular	Static	1.5	2.71
		Pseudo-Static	1.1	1.76
	Block	Static	1.5	2.76
		Pseudo-Static	1.1	1.80

As shown in Table E.2, all calculated factors of safety were significantly above the NRC recommended values of 1.5 for static conditions and 1.1 for pseudo-static conditions. The model profile figures and SLOPE/W output figures for static and pseudo-static loading conditions are shown in Figures E.3 through E.14.

APPENDIX F

SETTLEMENT AND LIQUEFACTION ANALYSES

F.1 BACKGROUND

This appendix presents results of settlement analyses and evaluation of liquefaction potential of tailings for the Energy Fuels Resources (USA) Inc. (EFRI) White Mesa Uranium Mill tailings disposal cells. These analyses are an update to the settlement and liquefaction analyses presented in MWH (2011) to address State of Utah, Division of Waste Management and Radiation Control (DWMRC) (formerly Utah Division of Radiation Control, DRC) interrogatories (DRC, 2012) and review comments on EFRI responses to 2012 interrogatories (DRC, 2013). These analyses also incorporate (1) the revised cover grading design, (2) results of cover material testing conducted in 2010 and 2012 (summarized in Attachment B of EFRI, 2012), (3) results of the recent site-specific probabilistic hazard analysis (presented in MWH, 2015a), (4) results of tailings testing conducted in 2013 (presented in MWH, 2015b), and (5) updated calculation methods for the seismic settlement and liquefaction potential.

Settlement analyses were conducted to evaluate settlement due to placement of final cover, dewatering of the tailings cells, long-term static (creep) settlement, and seismically induced (seismic) settlement. The results of these analyses were used to evaluate differential settlement and the potential for cover cracking. The settlement analyses are discussed in Section F.2. The tailings cells were also evaluated for liquefaction potential and discussion is provided in Section F.3.

The monolithic ET cover system evaluated in this appendix consists of the following layers from top to bottom:

- 0.5 ft (15 cm) Erosion Protection Layer (gravel-admixture)
- 3.5 ft (107 cm) Water Storage/Biointrusion/Frost Protection/Radon Attenuation Layer (loam to sandy clay)
- 3.0 to 4.0 ft (91 to 122 cm) Radon Attenuation Layer (highly compacted loam to sandy clay)
- 2.5 ft (75 cm) Radon Attenuation and Grading Layer (loam to sandy clay)

F.2 SETTLEMENT ANALYSES

F.2.1 Method of Analyses

General. One-dimensional (1-D) settlement analyses were conducted for the tailings in Cells 2 and 3 to estimate total potential future settlement of the tailings after placement of the final cover. The cone penetration testing (CPT) locations from the October 2013 tailings investigation (MWH, 2015b) were selected as the locations for the settlement analyses. The CPT locations are shown on Figure F.1, along with the settlement monument locations. All CPT locations were adjacent to settlement monuments.

The settlement analyses were conducted for two time periods as described below.

1. Settlement during active maintenance. This settlement was calculated as the settlement due to placement of the final cover and dewatering. Water levels during

active maintenance were assumed to be drawn down from water level elevations presented in MWH (2015b) for the October 2013 tailings elevation to five feet above the liner. EFRI proposes to dewater the tailings during active maintenance and draw down the water levels with in Cells 2 and 3 such that there are not issues with cover stability. This water level has been assumed as 5 feet for these analyses. Once dewatering to this water level has been completed, remaining primary consolidation due to placement of the cover will be very small.

2. Settlement after active maintenance. This settlement was calculated as the sum of settlement due to creep and seismic settlement. The water level within the tailings was assumed to be located five feet above the liner after active maintenance based EFRI's plan for dewatering during active maintenance for Cells 2 and 3.

1-D Column Geometry. Vertical soil profiles presented in MWH (2015b) for each CPT location were used in the 1-D consolidation analyses, with the water levels presented in that report being used for initial pore pressure conditions. This assumption is considered conservative since water levels will continue to decrease due to dewatering prior to final cover placement. Cover thicknesses are based on the cover design as listed above, with total cover thicknesses of 10.5 and 10 feet for Cells 2 and 3, respectively. The stress state for the layers within each column is calculated at the midpoint of each tailings layer. Additional vertical column geometry details are provided in Attachment F.1.

Total Settlement During Active Maintenance. Settlement during active maintenance is assumed to be due to primary consolidation caused by cover loading and dewatering (i.e. creep and initial compression are neglected). Settlement is calculated using the following equation:

$$S = \frac{C_C H}{1+e_0} \log \frac{\sigma'_f}{\sigma'_i}$$

Where:

S = settlement
C_c = compression index
H = thickness of tailings layer (ft)
e_i = initial void ratio of tailings
σ'_i = initial average effective overburden pressure (psf)
σ'_f = final effective vertical pressure (psf)

Total Settlement After Active Maintenance. Settlement after active maintenance is completed is assumed to be due to creep and seismic settlement.

Creep Settlement. Creep settlement was calculated using the method presented in Holtz and Kovacs (1981) and assuming a typical value for the ratio of the secondary compression index to the compression index (C_α/C_c) of 0.02 based on the upper bound average C_α estimated from laboratory testing on sand-slime and slime tailings (MWH, 2015b). The secondary settlements are based on a time period of 1,000 years.

Seismic Settlement. Seismic settlement was estimated using methods presented in Stewart et al. (2004), and seismic parameters presented in the site-specific probabilistic seismic hazard analysis for the site (MWH, 2015a). The mean peak ground acceleration (PGA) for reclaimed (long-term) conditions is 0.15 g for an average return period of 10,000 years. The mean seismic source is from a magnitude 5.5 event occurring 20 km from the site. The equations used from Stewart et al. (2004) are provided below.

Shear strain and related equations:

$$\gamma = \frac{1 + g_1 \cdot e^{g_2 \cdot P}}{1 + g_1} P \cdot 100 \text{ (units of \%)}$$

$$\text{PI} \approx 0: \quad g_1 = 0.199 \cdot (\sigma'/p_a)^{0.231} \quad g_2 = 10850 \cdot (\sigma'/p_a)^{-0.410}$$

$$\text{PI} \approx 15: \quad g_1 = 0.194 \cdot (\sigma'/p_a)^{0.265} \quad g_2 = 7490 \cdot (\sigma'/p_a)^{-0.418}$$

$$\text{PI} \approx 30: \quad g_1 = 4.0 \quad g_2 = 1400$$

$$\gamma_{eff} \frac{G_{eff}}{G_{max}} = \frac{0.65 \cdot PHA \cdot \sigma_0 \cdot r_d}{g \cdot G_{max}} \equiv P$$

Where:

γ: shear strain
PI: plasticity index
σ': effective stress
p_a : atmospheric pressure (calculated for an average elevation of 5,600 feet for the site)
G_{eff}: effective shear modulus
G_{max}: small strain shear modulus
PHA: peak horizontal acceleration
σ_o: total overburden pressure
r_d: reduction factor, ratio of actual shear stress at depth vs. theoretical "rigid body" shear stress
g: acceleration due to gravity

Volumetric strain at 15 cycles equation:

$$\varepsilon_{v,N=15} = a(\gamma_c - \gamma_{tv})^b$$

Where:

$\varepsilon_{v,\,N=15}$: volumetric strain at 15 cycles
a, b, and γ_{tv}: material-specific constants (estimated based on relative compaction, soil type, fines content, and plasticity using Figures 6.5 – 6.7 in Stewart et. al, 2004)
γ_c: shear strain (same as shear strain, γ, listed above)

Volumetric strain for design event:

$$\varepsilon_V = \varepsilon_{V,\ N=15} * C_n * 2$$

$$C_N = R\ln(N) + c$$

$$c = 1 - \ln(15)\times R$$

$$N = \frac{\left(\frac{\exp(b_1 + b_2(m - m^*))}{10^{1.5m+16.05}}\right)^{-\frac{1}{3}}}{4.9\cdot 10^6 \beta} + Sc_1 + rc_2$$

Where:

ε_V: volumetric strain for design event
C_N: normalized vertical strain
R: slope parameter (estimated as 0.36, 0.32, and 0.34 for soils with non-plastic fines, soils with low-plasticity fines, and soils with medium plasticity fines, respectively, as presented in Stewart et al., 2004 pages 86 through 89)
N: equivalent number of uniform strain cycles
c: slope parameter estimated from equation listed above
b_1: 1.53 (Stewart et al., 2004)
b_2: 1.51 (Stewart et al., 2004)
c_1: 0.75 (Stewart et al., 2004)
c_2: 0.095 (Stewart et al., 2004)
β: 3.2 (Stewart et al., 2004)
m: 5.8 (Stewart et al., 2004)*
m: design earthquake magnitude
r: site-source distance (km)
S: equal to 0 if rock or shallow soil (<20m) underlies the fill and 1 if >20m underlies the fill

F.2.2. Material Properties

EFRI conducted a tailings investigation of Cells 2 and 3 in October 2013 at the White Mesa Mill site to collect site-specific tailings data to supplement existing tailings data used for the settlement analyses. The results are presented in MWH (2015b). The tailings profiles and properties used for the settlement analyses are based on the results presented in MWH (2015b). Parameters used for the cover materials are based on cover material testing conducted in 2010 and 2012 (summarized in Attachment B of EFRI, 2012). Parameters used for the settlement analyses are summarized in Table F.1 and discussed in the following paragraph. Additional detail on soil properties and consolidation parameters used in the analyses are provided in Attachments F.1 through F.3.

Table F.1 Summary of Soil Parameters used for Settlement Analyses

Material Type	Initial Dry Density (pcf)	Specific Gravity	Initial void Ratio, e	Average Percent Passing No. 200 Sieve (%)	Com-pression Index, C_c	Secondary Com-pression Index, C_α
Erosion Protection Layer (topsoil)	100[1]	2.61[1]	0.61[2]	51[1]	0.14[3]	NA
Erosion Protection Layer (rock mulch)	106[1]	2.62[1]	0.54[2]	45[1]	0.14[3]	NA
Evapotransporation Cover Layer	100[1]	2.63[1]	0.64[2]	51[1]	0.14[3]	NA
High-Compaction Cover Layer	112[1]	2.63[1]	0.46[2]	51[1]	0.14[3]	NA
Platform Fill/Interim Cover	94[1]	2.63[1]	0.74[2]	51[1]	0.14[3]	NA
Sand Tailings	97[5]	2.70[5]	0.74[2]	18[5]	0.12[6]	0.002[4]
Sand-Slime Tailings	88[5]	2.80[5]	0.99[2]	47[5]	0.24[5]	0.005[4]
Slime Tailings	78[5]	2.86[5]	1.29 [2]	71[5]	0.28[5]	0.006[4]

[1]From laboratory values presented in EFRI (2012)
[2]Calculated value
[3] Calculated from empirical equation for soil types similar to cover material (as presented in Holtz and Kovacs, 1981).
[4] Estimated from laboratory results presented in MWH (2015b), upper bound average $C\alpha$ for sand-slime and slime tailings of 0.02
[5]From laboratory results presented in MWH (2015b)
[6]Based on lab testing performed on uranium tailings sands and presented in Keshian and Rager (1988)

Additional assumptions for soil parameters used in the analyses are provided below.

- For the consolidation, dewatering, and creep settlement analyses, the moist unit weight for all tailings layers (saturated and unsaturated) was estimated as the saturated unit weight which results in a conservative estimate of loading.
- For the consolidation, dewatering, and creep settlement analyses, properties of the layers of tailings between the liner and the bottom of the CPT depth were estimated as sand-slime tailings. The sand-slime tailings comprise approximately 65 percent of the total tailings in Cells 2 and 3.
- For calculating loading conditions for seismic settlement and evaluation of liquefaction, the moist unit weight for unsaturated tailings layers were estimated based on the long-term moisture content of the tailings as presented in the radon emanation modeling.
- Initial stress conditions for liquefaction analyses were estimated using CPT data from MWH (2015b) assuming the initial conditions in the future will be the same as in October 2013. This is conservative as it does not account for the effects of consolidation and aging that will occur in the tailings during the active maintenance period. For the seismic settlement analyses of Cell 3, the average shear wave velocities with depth measured for Cell 2 tailings were used in the analyses to partially account for consolidation and aging that will occur during this period. These values range from 460 to 600 feet per second. Tailings in Cell 2 were placed earlier than Cell 3 and have been actively dewatered since 2009. This use of the shear wave velocities measured in October 2013 is conservative for these analyses for both tailings cells since further densification of the tailings will occur during the active maintenance period.

F.2.3 Results

As discussed previously, settlement analyses were conducted for two time periods to estimate future settlement (1) settlement during active maintenance due to final cover placement and dewatering, and (2) settlement after active maintenance due to creep and seismic settlement. The results are summarized in Tables F.2 and F.3 and Figures F.2 and F.3. The spreadsheet calculations of are provided in Attachments F.1 (settlement due to dewatering of tailings and placement of final cover), F.2 (creep settlement), and F.3 (seismic settlement). Total settlement during active maintenance is conservatively estimated to range from 0.9 to 1.6 feet. Total remaining settlement due to dewatering from 5 feet above the liner to the liner is approximately 0.01 feet. Total potential future settlement due to creep is estimated to range from 0.05 to 0.09 feet, and due to seismic settlement is estimated to range from 0.23 to 0.62 feet. The total potential future long-term settlement due to creep and seismic settlement of the tailings is estimated to range from 0.29 to 0.71 feet**.** The estimates of total long term settlement were calculated by summing the static creep settlement estimate and the seismic settlement estimates. As such, these estimates are considered to be somewhat conservative as they are not independent (i.e. as long-term static creep progresses, void ratio reduction will occur and the potential for seismic settlement will reduce over time as a result).

Table F.2 Future Settlement During Active Maintenance

Location	Settlement due to Consolidation and Dewatering Prior to t_1 (ft)
2W2	1.09
2W3	1.15
2W4-C	1.29
2W5-C	1.26
2W6-S	1.29
2W7-C	1.17
2E1	1.30
3-1S	0.88
3-2C	1.19
3-3S	1.47
3-4N	1.56
3-6N	1.34
3-8N	1.03
3-8S	1.06

Notes:
t_1 corresponds to dewatering of the tailings to a level 5 feet above the liner

Table F.3 Future Settlement After Active Maintenance

Location	Settlement due to 1000 years of Creep (ft)	Seismic Settlement (ft)	Total Potential Future Settlement after Active Maintenance (ft)
2W2	0.06	0.35	0.41

3-8N	0.05	0.34	0.39
3-8S	0.08	0.35	0.43

F.2.4 Differential Settlement and Cover Cracking Potential

Differential Settlement. After placement of the final cover and during active maintenance, additional fill may be placed in any low areas to maintain positive drainage of the cover surface. Therefore, the critical time period where differential settlement is a concern for the cover grading (i.e. potential for slope reversal) is after active maintenance is complete. Potential maximum future settlement after active maintenance is estimated as 0.29 to 0.71 feet. Based on the settlement analyses results as shown on Figure F.2, the critical location for the ratio of maximum differential settlement over distance is estimated to occur between the CPT location 3-3S and the dike between Cells 3 and 4A (conservatively assuming no settlement of the dike fill). Although the differential settlement is higher between CPT location 3-4N and 3-6N and the dike between Cells 2 and 3, differential settlement at these location would result in an increase in cover slope, therefore the former location is more critical for slope reversal. Locations on Cell 2 with higher settlement (2W4-C, 2W5-C, 2W6-S) than the 3-3S location are located within the center of Cell 2, however the highest differential settlement associated with these points is lower than the selected critical case.

The total potential differential settlement between 3-3S and the dike between Cells 3 and 4A is 0.50 feet over a distance of approximately 175 feet. The estimated differential settlement is sufficiently low such that ponding and slope reversal is not expected to occur. These calculations are based on conservative assumptions for seismic settlement with little to no credit taken for densification of tailings prior to placement of final cover and during active maintenance of the tailings cells. In addition, as mentioned above, creep and seismic settlement are not independent, however they have been treated as such in the calculations. Actual differential settlement for long-term (after active maintenance) conditions is expected to be lower.

Cover Cracking. Cover cracking analyses were performed for the highly-compacted radon barrier. The critical location for the cover cracking analyses for maximum differential settlement due to final cover placement, dewatering of tailings, creep, and a seismic event is 2.27 feet between the settlement monument 3-4N and dike between Cells 2 and 3 as shown on Figure F.3. This location has the maximum differential settlement over the shortest horizontal distance. The maximum differential settlement, assuming there is no settlement of the dike, is 2.27 feet. The horizontal distance between the two locations is approximately 150 feet.

Morrison-Knudsen Environmental Corporation (1993) presents a method for determining the tensile strain required to cause cracking of the radon barrier as a function of the plasticity index (PI) of the soil. The tensile strain at cracking is calculated by the equation below:

$$\varepsilon_f (\%) = 0.05 + 0.003 \times (PI)$$

where: $\varepsilon_f(\%)$ = tensile strain to cause cracking of the radon barrier
PI = plasticity index of radon barrier

The PI value for the highly compacted radon attenuation layer was estimated as the weighted average (based on soil volumes) of the measured PIs (11) for composite samples collected during the 2010 and 2012 borrow investigations (see Attachment B of EFRI, 2012). Using this value for PI, the minimum tensile strain that will induce cracking is 0.08 percent. The maximum settlement-induced horizontal tensile strain on the radon attenuation layer must be less than 0.08 percent so that cover cracking will not occur.

The horizontal movement at the top of the radon barrier can be calculated based on the following equation (Lee and Shen, 1969), which is referenced in NUREG 1620 (NRC, 2003) for cover cracking analysis:

$$m = \frac{2}{3} H\alpha$$

where: m = horizontal movement in feet
H = thickness of relatively incompressible material (in this analysis H is the thickness of the highly compacted radon barrier)
α = local slope of the settlement profile (expressed as decimal fraction)

Horizontal movement at the maximum tailing thickness is calculated to be 0.035 feet using a maximum thickness of relatively incompressible material of 3.5 feet, and a total differential settlement of 2.27 feet over 150 feet. The thickness of relatively incompressible material was estimated assuming a maximum 3.5-ft highly compacted radon barrier for Cell 3. The peak horizontal movement is assumed to be twice the average horizontal movement based on relationships presented in Gourc et al. (2010) and Rajesh and Viswanadham (2010). The peak horizontal movement is then calculated as 0.07.

The horizontal strain between any two settlement monitoring locations is the maximum horizontal movement divided by the horizontal distance (0.07 ft/150 ft). Using these values, the maximum horizontal strain is calculated as 0.05 percent. This value is lower than the maximum allowable strain of 0.08 percent and indicates that cracking of the radon attenuation layer due to settlement is not expected.

F.3 LIQUEFACTION ANALYSIS

F.3.1 Method of Analysis

Two procedures were used to evaluate the potential for liquefaction of the tailings based on the results of the CPT soundings. These methods (Idriss and Boulanger, 2008; Youd et al., 2001) are described below. The average factor of safety calculated from the two methods was used as the factor of safety for evaluating the liquefaction potential of the tailings.

Idriss and Boulanger (2008). The Idriss and Boulanger (2008) liquefaction triggering method estimates the cyclic stress ratio (CSR) based on the seismic design criteria and estimates the cyclic resistance ratio (CRR) based on the CPT readings and site conditions. CSR is calculated using a simplified procedure to estimate earthquake induced stresses, calculated using the following relationship:

$$CSR_{M=7.5,\sigma'_{vc}=1} = 0.65\frac{a_{max}}{g}\frac{\sigma_{vc}}{\sigma'_{vc}}\frac{1}{MSF}\frac{1}{K_\sigma}\frac{1}{K_\alpha}$$

Where:

a_{max}: maximum horizontal ground surface acceleration
σ_{vc}': effective vertical confining stress
σ_{vc}: total vertical confining stress
MSF: earthquake magnitude scaling factor
K_σ: overburden correction factor
K_α: static shear stress correction factor
g: acceleration due to gravity

The equations for the correction factors applied to the CSR for this evaluation are the following:

$$r_d = \exp(\alpha(z) + \beta(z)M)$$

$$\alpha(z) = -1.012 - 1.126\sin\left(\frac{z}{11.73} + 5.133\right)$$

$$\beta(z) = 0.106 + 0.118\sin\left(\frac{z}{11.28} + 5.142\right)$$

$$\text{MSF} = 6.9\exp\left(\frac{-M}{4}\right) - 0.058 \quad \leq 1.8$$

$$K_\sigma = 1 - C_\sigma \ln\left(\frac{\sigma'_{vc}}{P_a}\right) \leq 1.1$$

$$C_\sigma = \frac{1}{37.3 - 8.27(q_{c1N})^{0.264}} \leq 0.3$$

Where:

r_d: shear stress reduction coefficient
q_{c1N}: tip resistance normalized to atmospheric pressure and overburden pressure
z: depth below ground surface

P_a: atmospheric pressure (calculated for an average elevation of 5,600 feet for the site)
M: design earthquake magnitude

The tailings pile was evaluated assuming essentially flat ground, and ignored the effects of the slope at the edge of the tailings pile. Thus, a static shear stress correction factor of $K_\alpha=1$ was used for all calculations.

The relationship for CRR is based on liquefaction case histories and is expressed as:

$$\mathrm{CRR}_{M=7.5,\sigma'_{vc}=1} = \exp\left(\frac{q_{c1Ncs}}{540} + \left(\frac{q_{c1Ncs}}{67}\right)^2 - \left(\frac{q_{c1Ncs}}{80}\right)^3 + \left(\frac{q_{c1Ncs}}{114}\right)^4 - 3\right)$$

Where:

q_{c1Ncs}: equivalent clean-sand corrected normalized tip resistance

$$q_{c1Ncs} = q_{c1N} + \Delta q_{c1N}$$

$$\Delta q_{c1N} = \left(5.4 + \frac{q_{c1N}}{16}\right) \cdot \exp\left(1.63 + \frac{9.7}{\mathrm{FC}+0.01} - \left(\frac{15.7}{\mathrm{FC}+0.01}\right)^2\right)$$

FC = Fines Content in %

The factor of safety against liquefaction was computed as:

$$FS_{liq} = \frac{\mathrm{CRR}_{M=7.5,\sigma'_{vc}=1}}{\mathrm{CSR}_{M=7.5,\sigma'_{vc}=1}}$$

The correlation between CSR, CRR, and q_{c1N} is shown in Figure 67 of Idriss and Boulanger (2008).

Youd et al. (2001). The Youd et al. (2001) liquefaction triggering method estimates the CSR based on the seismic design criteria and estimates the CRR based on the CPT readings and site conditions. CSR is calculated using a simplified procedure to estimate earthquake induced stresses, calculated using the following relationship:

$$CSR_{M=7.5,\sigma'_{vc}=1} = 0.65\frac{a_{max}}{g}\frac{\sigma_{vc}}{\sigma'_{vc}}\frac{1}{MSF}\frac{1}{K_\sigma}\frac{1}{K_\alpha}$$

Where:

a_{max}: maximum horizontal ground surface acceleration
σ_{vc}': effective vertical confining stress
σ_{vc}: total vertical confining stress
r_d: shear stress reduction coefficient

MSF: earthquake magnitude scaling factor
K_σ: overburden correction factor
K_α: static shear stress correction factor
g: acceleration due to gravity

The equations for the correction factors applied to the CSR for this evaluation are the following:

$$r_d = 1.0 - 0.00765z \quad \text{for } z \leq 9.15 \text{ m}$$

$$r_d = 1.174 - 0.0267z \quad \text{for } 9.15 \text{ m} < z \leq 23 \text{ m}$$

Revised Idriss Scaling Factor: $\text{MSF} = 10^{2.24}/M_w^{2.56}$

$$K_\sigma = (\sigma'_{vo}/P_a)^{(f-1)}$$

Where:

z: Depth below ground surface
M_w: Design earthquake magnitude
P_a: Atmospheric Pressure
σ_{vc}': effective vertical overburden pressure
f=0.7 to 0.8 for 40% ≤ relative density, D_r ≤ 60%
0.6 to 0.7 for 60% < relative density, D_r ≤ 80%

$$D_r = \sqrt{\frac{q_{c1n}}{300}}$$

The tailings pile was evaluated assuming flat ground conditions. Thus, a static shear stress correction factor of *K_α=1* was used for all calculations.

The relationship for CRR is based on liquefaction case histories and is expressed as:

$$\text{If } (q_{c1N})_{cs} < 50 \quad \text{CRR}_{7.5} = 0.833[(q_{c1N})_{cs}/1{,}000] + 0.05$$
$$\text{If } 50 \leq (q_{c1N})_{cs} < 160 \quad \text{CRR}_{7.5} = 93[(q_{c1N})_{cs}/1{,}000]^3 + 0.08$$

Where:

$q_{c1Ncs} = K_c * q_{c1N}$

$$\text{for } I_c \leq 1.64 \quad K_c = 1.0$$

$$\text{for } I_c > 1.64 \quad K_c = -0.403I_c^4 + 5.581I_c^3 - 21.63I_c^2 + 33.75I_c - 17.88$$

The factor of safety against liquefaction was computed as:

$$FS_{liq} = \frac{\mathrm{CRR}_{M=7.5,\sigma'_{vc}=1}}{\mathrm{CSR}_{M=7.5,\sigma'_{vc}=1}}$$

The correlation between CSR, CRR, and q_{c1N} is shown in Figure 4 of Youd et al. (2001).

F.3.2. Material Properties

Liquefaction evaluation was performed for all CPT locations from the October 2013 tailings investigation (MWH, 2015b). The liquefaction evaluation used the same assumptions for soil profile, water table elevation, and density of the tailings material as described above for the long-term settlement analyses. Other parameters used for the evaluation were based on CPT data as presented in Attachment F.4 and as outlined in Idriss and Boulanger (2008) and Youd et al. (2001). It is assumed that the compacted cover materials are not susceptible to liquefaction and therefore were not included in the analyses.

F.3.3. Site Seismicity

Results of the site-specific probabilistic seismic hazard analysis presented in MWH (2015a) were used in the analysis of liquefaction potential. The mean peak ground acceleration for reclaimed (long-term) conditions is 0.15 g for an average return period of 10,000 years. The mean seismic source is from a magnitude 5.5 event occurring 20 km from the site.

F.3.4 Results

Table F.4 presents a summary of the results of the liquefaction analysis. Further details of the calculation can be found in Attachment F.4.

Table F.4 Summary of Liquefaction Results

Location	Minimum Factor of Safety
2W2	2.58
2W3	2.37
2W4-C	2.11
2W5-C	2.08
2W6-S	2.24
2W7-C	2.10
2E1	1.96
3-1S	2.41
3-2C	2.59
3-3S	2.36
3-4N	2.46
3-6N	2.30
3-8N	2.84
3-8S	2.38

Based on the factors of safety presented in Table F.4, the tailings are judged not to be susceptible to earthquake-induced liquefaction. The computed factors of safety against liquefaction range from 2.0 to 2.6.

F.4 CONCLUSIONS

Evaluation total settlement due to final cover placement and dewatering indicates potential future settlement during the active maintenance to range from approximately 0.9 to 1.6 feet. During this time, additional fill can be placed in any low areas in order to maintain positive drainage of the cover surface. The total predicted future long-term settlement that could occur (due to creep and seismic settlement) after the maintenance time period is complete is estimated to range from approximately 0.3 to 0.7 feet. The estimates of total long-term settlement were calculated by summing the static creep settlement estimate and the seismic settlement estimates. As such, these estimates are considered to be somewhat conservative as they are not independent (i.e. as long-term static creep progresses, void ratio reduction will occur and the potential for seismic settlement will reduce over time as a result). The estimated differential settlement after completion of active maintenance is sufficiently low that slope reversal and ponding is not expected to occur on a cover slope of 0.5 to 1.0 percent. In addition, the results indicate that cracking of the highly-compacted radon barrier due to settlement-induced strains is not expected. The results of the liquefaction analyses indicate the tailings are not susceptible to earthquake-induced liquefaction.

Similar results are expected for Cells 4A and 4B. Although Cells 4A and 4B have higher tailings thicknesses, these cells have a more effective dewatering systems and a low water level requirement for dewatering. These cells also have a slightly steeper average cover slope (approximately 0.8 percent) than Cells 2 and 3.

SETTLEMENT CALCULATIONS FOR SETTLEMENT DUE TO DEWATERING THE TAILINGS AND PLACMENT OF THE FINAL COVER

Notes

t_0 corresponds to beginning of final cover placement — Assumes 99% of consolidation due to existing stress conditions has taken place

t_1 corresponds to dewatering of the tailings to a level 5 feet above the liner

t_2 corresponds to completion of dewatering

SOIL PROPERTIES

TAILINGS

	Specific Gravity, G_s	
2.70	Specific gravity of tailing sands, $G_{s\text{-}TSand}$	Based on lab testing performed on uranium tailings sands and presented in Keshian and Rager (1988)
2.80	Specific gravity of tailing sand-slimes, $G_{s\text{-}TS\text{-}S}$	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
2.86	Specific gravity of tailing slimes, $G_{s\text{-}TSlime}$	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
	Fines Content	
18%	Fines content of tailings sands (%)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
47%	Fines content of tailings sand-slimes (%)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
71%	Fines content of tailings slimes (%)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
	Dry Unit Weight, γ_d	
97	In-situ dry unit weight of tailings sands at t_0, $\gamma_{d0\text{-}Tsand}$ (pcf)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
88	In-situ dry unit weight of tailings sand-slimes at t_0, $\gamma_{d0\text{-}TS\text{-}S}$ (pcf)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
78	In-situ dry unit weight of tailings slimes at t_0, $\gamma_{d0\text{-}Tslime}$ (pcf)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
	Saturated Unit Weight, γ_{sat}	
123	In-situ saturated unit weight of tailings sands at t_0, $\gamma_{sat0\text{-}Tsand}$ (pcf)	Calculated
119	In-situ saturated unit weight of tailings sand-slimes at t_0, $\gamma_{sat0\text{-}TS\text{-}S}$ (pcf)	Calculated
113	In-situ saturated unit weight of tailings slimes at t_0, $\gamma_{sat0\text{-}Tslime}$ (pcf)	Calculated
	Moist Unit Weight, γ_m	
123	Moist unit weight of tailings sands, $\gamma_{m\text{-}Tsand}$ (pcf)	Calculated, assuming 100% degree of saturation (conservative estimate of loading from these layers)
119	Moist unit weight of tailings sand-slimes, $\gamma_{m\text{-}TS\text{-}S}$ (pcf)	Calculated, assuming 100% degree of saturation (conservative estimate of loading from these layers)
113	Moist unit weight of tailings slimes, $\gamma_{m\text{-}Tslime}$ (pcf)	Calculated, assuming 100% degree of saturation (conservative estimate of loading from these layers)
	Void Ratio, e	
0.74	Void ratio of tailing sands at t_0, $e_{0\text{-}TSand}$	Calculated
0.99	Void ratio of tailing sand-slimes at t_0, $e_{0\text{-}TS\text{-}S}$	Calculated
1.29	Void ratio of tailing slimes at t_0, $e_{0\text{-}TSlime}$	Calculated
	Saturated Water Content, w_{Sat}	
27%	Saturated water content of tailings sands at t_0, $w_{sat0\text{-}TSand}$ (%)	Calculated
35%	Saturated water content of tailings sand-slimes at t_0, $w_{sat0\text{-}TS\text{-}S}$ (%)	Calculated
45%	Saturated water content of tailings slimes at t_0, $w_{sat0\text{-}TSlime}$ (%)	Calculated
	Water Content of Moist Tailings, $w_{m\text{-}T}$	
27%	Water content of moist tailings sands, $w_{m\text{-}TSand}$ (%)	Calculated, assuming 100% saturation (conservative value used to estimate loading from these layers, actual long-term water content will be lower)
35%	Water content of moist tailings sand-slimes, $w_{m\text{-}TS\text{-}S}$ (%)	Calculated, assuming 100% saturation (conservative value used to estimate loading from these layers, actual long-term water content will be lower)
45%	Water content of moist tailings slimes, $w_{m\text{-}TSlime}$ (%)	Calculated, assuming 100% saturation (conservative value used to estimate loading from these layers, actual long-term water content will be lower)
	Compression Index, C_c	
0.12	Compression index of tailings sands, $C_{c\text{-}TSand}$	Based on lab testing performed on uranium tailings sands and presented in Keshian and Rager (1988)
0.24	Compression index of tailings sand-slimes, $C_{c\text{-}TS\text{-}S}$	Median value from lab testing of tailings sand-slimes samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
0.28	Compression index of tailings slimes, $C_{c\text{-}TSlime}$	Median value from lab testing of tailings slimes samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
	Other	
62.4	Unit Weight of Water, γ_W	
5.0	Height of water table above liner at t_1, $H_{sat\text{-}1}$ (ft)	Assumed for end of active maintenance
0.0	Height of water table above liner at t_2, $H_{sat\text{-}2}$ (ft)	

82.4	Atmospheric Pressure, P_a (kPa)	Calculated assuming elev=5600' amsl. http://www.engineeringtoolbox.com/air-altitude-pressure-d_462.html
1722.0	Atmospheric Pressure, P_a (psf)	Unit conversion calculation
5.2%	Long-term moisture content of tailings, $w_{tailings}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
0.020	Ratio of Secondary Compression Index to Primary Compression Index, C_α/C_c	Estimated from laboratory results presented in MWH (2015b), upper bound average C_α for sand-slime and slime tailings of 0.02

COVER SOIL

Specific Gravity, G_s		
2.61	Specific gravity of topsoil, $G_{s\text{-}Topsoil}$	From Attachment H - Radon Emanation Modeling including with this submittal
2.62	Specific gravity of rock mulch, $G_{s\text{-}mulch}$	From Attachment H - Radon Emanation Modeling including with this submittal
2.63	Specific gravity of cover soil, $G_{s\text{-}cover}$	From Attachment H - Radon Emanation Modeling including with this submittal
Unit Weight, γ		
118.0	Maximum dry unit weight of cover soil $\gamma_{cover\text{-}max}$ (pcf)	Average calculated from laboratory testing results (UWM, 2012)
100.7	Moist unit weight of cover soil at 80% relative compaction, $\gamma_{cover80}$ (pcf)	Calculated
107.0	Moist unit weight of cover soil at 85% relative compaction, $\gamma_{cover85}$ (pcf)	Calculated
119.6	Moist unit weight of cover soil at 95% relative compaction, $\gamma_{cover95}$ (pcf)	Calculated
127.5	Saturated unit weight of cover soil at 80% relative compaction, $\gamma_{cover80\text{-}sat}$ (pcf)	Calculated
100	Dry unit weight of topsoil layer at 85% relative compaction, $\gamma_{topsoil5}$ (pcf)	From Attachment H - Radon Emanation Modeling including with this submittal
105	Moist unit weight of topsoil layer at 85% relative compaction, $\gamma_{topsoil5}$ (pcf)	Calculated
106	Dry unit weight of rock mulch layer at 85% relative compaction, $\gamma_{mulch85}$ (pcf)	From Attachment H - Radon Emanation Modeling including with this submittal
110	Moist unit weight of rock mulch layer at 85% relative compaction, $\gamma_{mulch85}$ (pcf)	From Attachment H - Radon Emanation Modeling including with this submittal
Void Ratio, e		
0.74	Void Ratio of cover soil at 80% relative compaction, $e_{cover80}$	Calculated
0.64	Void Ratio of cover soil at 85% relative compaction, $e_{cover85}$	Calculated
0.46	Void Ratio of cover soil at 95% relative compaction, $e_{cover95}$	Calculated
0.61	Void Ratio of topsoil at 85% relative compaction, $e_{topsoil85}$	Calculated from porosity presented in Attachment H - Radon Emanation Modeling including with this submittal
0.54	Void Ratio of rock mulch at 85% relative compaction, $e_{mulch85}$	Calculated from porosity presented in Attachment H - Radon Emanation Modeling including with this submittal
Other		
6.7%	Long-term moisture content of cover soil, w_{cover} (%)	Estimated based on measured 15bar water content. (UWM, 2012)
5.2%	Long-term moisture content of topsoil, $w_{topsoil}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
4.0%	Long-term moisture content of rock mulch, $w_{rockmulch}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
0.14	Compression index of cover soil, $C_{c\text{-}cover}$	Calculated from empirical equation for soil types similar to cover material (as presented in Holtz and Kovacs, 1981. Page 341). $C_c = 0.30*(e_0\text{-}0.27)$

FINAL COVER

5620.47	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)	From cover deisgn grading plan AutoCAD file
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after placement (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
3.50	Thickness of Water Storage/Rooting Zone (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
3.50	Thickness of High Compaction Layer (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
0.41	Thickness of Random/Platform Fill on on top of existing interim cover (ft)	Calculated
887.10	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)	Calculated

PROFILE INFORMATION

5608.00	Water surface elevation during CPT investigation (ft amsl)	From on-site investigation (Tailings Data Analysis Report. MWH, 2015)
5604.4	Water surface elevation at t_0 (ft amsl)	Minimum of 5' below top of tailings or water surface elevation at time of CPT testing (2013
5595.59	Water surface elevation at t_1 (ft amsl)	
5590.59	Water surface elevation at t_2 (ft amsl)

Total Consolidtion of Profile at t_1, $\delta_{c\text{-}t1}$ (ft):	**1.06**
Total Consolidtion of Profile at t_2, $\delta_{c\text{-}t2}$ (ft):	**0.01**

Notes:

[1] From on-site investigation (Tailings Data Analysis Report. MWH, 2015)

ATTACHMENT F.2

CREEP SETTLEMENT CALCULATIONS

Notes

	t_0 corresponds to beginning of final cover placement	Assumes 99% of consolidation due to existing stress conditions has taken place
	t_1 corresponds to dewatering of the tailings to a level 5 feet above the liner	
	t_2 corresponds to completion of dewatering	

SOIL PROPERTIES

TAILINGS

Specific Gravity, G_s		
2.70	Specific gravity of tailing sands, $G_{s\text{-}TSand}$	Based on lab testing performed on uranium tailings sands and presented in Keshian and Rager (1988)
2.80	Specific gravity of tailing sand-slimes, $G_{s\text{-}TS\text{-}S}$	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
2.86	Specific gravity of tailing slimes, $G_{s\text{-}TSlime}$	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
Fines Content		
18%	Fines content of tailings sands (%)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
47%	Fines content of tailings sand-slimes (%)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
71%	Fines content of tailings slimes (%)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
Dry Unit Weight, γ_d		
97	In-situ dry unit weight of tailings sands at t_0, $\gamma_{d0\text{-}Tsand}$ (pcf)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
88	In-situ dry unit weight of tailings sand-slimes at t_0, $\gamma_{d0\text{-}TS\text{-}S}$ (pcf)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
78	In-situ dry unit weight of tailings slimes at t_0, $\gamma_{d0\text{-}Tslime}$ (pcf)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
Saturated Unit Weight, γ_{sat}		
123	In-situ saturated unit weight of tailings sands at t_0, $\gamma_{sat0\text{-}Tsand}$ (pcf)	Calculated
119	In-situ saturated unit weight of tailings sand-slimes at t_0, $\gamma_{sat0\text{-}TS\text{-}S}$ (pcf)	Calculated
113	In-situ saturated unit weight of tailings slimes at t_0, $\gamma_{sat0\text{-}Tslime}$ (pcf)	Calculated
Moist Unit Weight, γ_m		
123	Moist unit weight of tailings sands, $\gamma_{m\text{-}Tsand}$ (pcf)	Calculated, assuming 100% degree of saturation (conservative estimate of loading from these layers)
119	Moist unit weight of tailings sand-slimes, $\gamma_{m\text{-}TS\text{-}S}$ (pcf)	Calculated, assuming 100% degree of saturation (conservative estimate of loading from these layers)
113	Moist unit weight of tailings slimes, $\gamma_{m\text{-}Tslime}$ (pcf)	Calculated, assuming 100% degree of saturation (conservative estimate of loading from these layers)
Void Ratio, e		
0.74	Void ratio of tailing sands at t_0, $e_{0\text{-}TSand}$	Calculated
0.99	Void ratio of tailing sand-slimes at t_0, $e_{0\text{-}TS\text{-}S}$	Calculated
1.29	Void ratio of tailing slimes at t_0, $e_{0\text{-}TSlime}$	Calculated
Saturated Water Content, w_{Sat}		
27%	Saturated water content of tailings sands at t_0, $w_{sat0\text{-}TSand}$ (%)	Calculated
35%	Saturated water content of tailings sand-slimes at t_0, $w_{sat0\text{-}TS\text{-}S}$ (%)	Calculated
45%	Saturated water content of tailings slimes at t_0, $w_{sat0\text{-}TSlime}$ (%)	Calculated
Water Content of Moist Tailings, $w_{m\text{-}T}$		
27%	Water content of moist tailings sands, $w_{m\text{-}TSand}$ (%)	Calculated, assuming 100% saturation (conservative value used to estimate loading from these layers, actual long-term water content will be lower)
35%	Water content of moist tailings sand-slimes, $w_{m\text{-}TS\text{-}S}$ (%)	Calculated, assuming 100% saturation (conservative value used to estimate loading from these layers, actual long-term water content will be lower)
45%	Water content of moist tailings slimes, $w_{m\text{-}TSlime}$ (%)	Calculated, assuming 100% saturation (conservative value used to estimate loading from these layers, actual long-term water content will be lower)
Compression Index, C_c		
0.12	Compression index of tailings sands, $C_{c\text{-}TSand}$	Based on lab testing performed on uranium tailings sands and presented in Keshian and Rager (1988)
0.24	Compression index of tailings sand-slimes, $C_{c\text{-}TS\text{-}S}$	Median value from lab testing of tailings sand-slimes samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
0.28	Compression index of tailings slimes, $C_{c\text{-}TSlime}$	Median value from lab testing of tailings slimes samples obtained on-site (Tailings Data Analysis Report. MWH, 2015)
Normalized Blow Count, N_{60}		
17	Normalized Blow Count for saturated tailings sands, $N_{60\text{-}TSand}$	
7	Normalized Blow Count for saturated tailings sand-slimes, $N_{60\text{-}TS\text{-}S}$	
4	Normalized Blow Count for saturated tailings slimes, $N_{60\text{-}Tslime}$	

23	Normalized Blow Count for unsaturated tailings sands, $N_{60\text{-}TSand}$	
14	Normalized Blow Count for unsaturated tailings sand-slimes, $N_{60\text{-}TS\text{-}S}$	Blow counts for material types calculated using method presented in Guide to Cone Penetration Testing for Geotechnical Engineering, 5th Ed. (Robertson and Cabal, 2012).
10	Normalized Blow Count for unsaturated tailings slimes, $N_{60\text{-}Tslime}$	
Other		
62.4	Unit Weight of Water, γ_W	
5.0	Height of water table above liner at t_1, $H_{sat\text{-}1}$ (ft)	Assumed for end of active maintenance
0.0	Height of water table above liner at t_2, $H_{sat\text{-}2}$ (ft)	
82.4	Atmospheric Pressure, P_a (kPa)	Calculated assuming elev=5600' amsl. http://www.engineeringtoolbox.com/air-altitude-pressure-d_462.html
1722.0	Atmospheric Pressure, P_a (psf)	Unit conversion calculation
5.2%	Long-term moisture content of tailings, $w_{tailings}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
0.020	Ratio of Secondary Compression Index to Primary Compression Index, C_α/C_c	Estimated from laboratory results presented in MWH (2015b), upper bound average $C\alpha$ for sand-slime and slime tailings of 0.02

COVER SOIL

Specific Gravity, G_s		
2.61	Specific gravity of topsoil, $G_{s\text{-}Topsoil}$	From Attachment H - Radon Emanation Modeling including with this submittal
2.62	Specific gravity of rock mulch, $G_{s\text{-}mulch}$	From Attachment H - Radon Emanation Modeling including with this submittal
2.63	Specific gravity of cover soil, $G_{s\text{-}cover}$	From Attachment H - Radon Emanation Modeling including with this submittal
Unit Weight, γ		
118.0	Maximum dry unit weight of cover soil $\gamma_{cover\text{-}max}$ (pcf)	Average calculated from laboratory testing results (UWM, 2012)
100.7	Moist unit weight of cover soil at 80% relative compaction, $\gamma_{cover80}$ (pcf)	Calculated
107.0	Moist unit weight of cover soil at 85% relative compaction, $\gamma_{cover85}$ (pcf)	Calculated
119.6	Moist unit weight of cover soil at 95% relative compaction, $\gamma_{cover95}$ (pcf)	Calculated
127.5	Saturated unit weight of cover soil at 80% relative compaction, $\gamma_{cover80\text{-}sat}$ (pcf)	Calculated
100	Dry unit weight of topsoil layer at 85% relative compaction, $\gamma_{topsoil5}$ (pcf)	From Attachment H - Radon Emanation Modeling including with this submittal
105	Moist unit weight of topsoil layer at 85% relative compaction, $\gamma_{topsoil5}$ (pcf)	Calculated
106	Dry unit weight of rock mulch layer at 85% relative compaction, $\gamma_{mulch85}$ (pcf)	From Attachment H - Radon Emanation Modeling including with this submittal
110	Moist unit weight of rock mulch layer at 85% relative compaction, $\gamma_{mulch85}$ (pcf)	From Attachment H - Radon Emanation Modeling including with this submittal
Void Ratio, e		
0.74	Void Ratio of cover soil at 80% relative compaction, $e_{cover80}$	Calculated
0.64	Void Ratio of cover soil at 85% relative compaction, $e_{cover85}$	Calculated
0.46	Void Ratio of cover soil at 95% relative compaction, $e_{cover95}$	Calculated
0.61	Void Ratio of topsoil at 85% relative compaction, $e_{topsoil85}$	Calculated from porosity presented in Attachment H - Radon Emanation Modeling including with this submittal
0.54	Void Ratio of rock mulch at 85% relative compaction, $e_{mulch85}$	Calculated from porosity presented in Attachment H - Radon Emanation Modeling including with this submittal
Other		
6.7%	Long-term moisture content of cover soil, w_{cover} (%)	Estimated based on measured 15bar water content. (UWM, 2012)
5.2%	Long-term moisture content of topsoil, $w_{topsoil}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
4.0%	Long-term moisture content of rock mulch, $w_{rockmulch}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
0.14	Compression index of cover soil, $C_{c\text{-}cover}$	Calculated from empirical equation for soil types similar to cover material (as presented in Holtz and Kovacs, 1981. Page 341). $C_c = 0.30*(e_0\text{-}0.27)$

FINAL COVER		
5625.87	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)	From cover deisgn grading plan AutoCAD file
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after placement (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
3.50	Thickness of Water Storage/Rooting Zone (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
4.00	Thickness of High Compaction Layer (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
2.02	Thickness of Random/Platform Fill on on top of existing interim cover (ft)	Calculated
1111.60	Additional Stress due to Final Cover Placement $\Delta\sigma_{FC}$ (psf)	Calculated

PROFILE INFORMATION		
5613.10	Water surface elevation during CPT investigation (ft amsl)	From on-site investigation (Tailings Data Analysis Report. MWH, 2015)
5607.7	Water surface elevation at t_0 (ft amsl)	Minimum of 5' below top of tailings or water surface elevation at time of CPT testing (2013).
5598.51	Water surface elevation at t_1 (ft amsl)	
5593.51	Water surface elevation at t_2 (ft amsl)

FINAL COVER

5626.27	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)	From cover deisgn grading plan AutoCAD file
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after placement (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
3.50	Thickness of Water Storage/Rooting Zone (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
4.00	Thickness of High Compaction Layer (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
2.55	Thickness of Random/Platform Fill on on top of existing interim cover (ft)	Calculated
1164.98	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)	Calculated

PROFILE INFORMATION

5613.80	Water surface elevation during CPT investigation (ft amsl)	From on-site investigation (Tailings Data Analysis Report. MWH, 2015)
5607.6	Water surface elevation at t_0 (ft amsl)	Minimum of 5' below top of tailings or water surface elevation at time of CPT testing (2013).
5597.75	Water surface elevation at t_1 (ft amsl)	
5592.75	Water surface elevation at t_2 (ft amsl)	

2W3

CREEP SETTLEMENT

Notes:

[1] From on-site investigation (Tailings Data Analysis Report. MWH, 2015)

2W7-C

FINAL COVER

5626.65	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)	From cover deisgn grading plan AutoCAD file
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after placement (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
3.50	Thickness of Water Storage/Rooting Zone (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
4.00	Thickness of High Compaction Layer (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
-0.95	Thickness of Random/Platform Fill on on top of existing interim cover (ft)	Calculated
812.44	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)	Calculated

PROFILE INFORMATION

5613.10	Water surface elevation during CPT investigation (ft amsl)	From on-site investigation (Tailings Data Analysis Report. MWH, 2015)
5611.5	Water surface elevation at t_0 (ft amsl)	Minimum of 5' below top of tailings or water surface elevation at time of CPT testing (2013).
5595.40	Water surface elevation at t_1 (ft amsl)	
5590.40	Water surface elevation at t_2 (ft amsl)	

2W7-C

3-1S

FINAL COVER

5620.47	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)	From cover deisgn grading plan AutoCAD file
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after placement (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
3.50	Thickness of Water Storage/Rooting Zone (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
3.50	Thickness of High Compaction Layer (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
0.41	Thickness of Random/Platform Fill on on top of existing interim cover (ft)	Calculated
887.10	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)	Calculated

PROFILE INFORMATION

5608.00	Water surface elevation during CPT investigation (ft amsl)	From on-site investigation (Tailings Data Analysis Report. MWH, 2015)
5604.4	Water surface elevation at t_0 (ft amsl)	Minimum of 5' below top of tailings or water surface elevation at time of CPT testing (2013).
5595.59	Water surface elevation at t_1 (ft amsl)	
5590.59	Water surface elevation at t_2 (ft amsl)	

3-1S

CREEP SETTLEMENT

FINAL COVER		
5623.62	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)	From cover deisgn grading plan AutoCAD file
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after placement (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
3.50	Thickness of Water Storage/Rooting Zone (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
3.50	Thickness of High Compaction Layer (ft)	From Appendix C - Radon Emanation Modeling (MWH, 2015)
8.68	Thickness of Random/Platform Fill on on top of existing interim cover (ft)	Calculated
1720.10	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)	Calculated

PROFILE INFORMATION		
5604.20	Water surface elevation during CPT investigation (ft amsl)	From on-site investigation (Tailings Data Analysis Report. MWH, 2015)
5599.3	Water surface elevation at t_0 (ft amsl)	Minimum of 5' below top of tailings or water surface elevation at time of CPT testing (2013).
5590.44	Water surface elevation at t_1 (ft amsl)	
5585.44	Water surface elevation at t_2 (ft amsl)	

3-6N

CREEP SETTLEMENT

Soil Layer	Material Type [1]	Elevation at Top of Layer at t_1, $z_{i\text{-}top1}$ (ft amsl)	Elevation at Midpoint of Layer at t_1, $z_{i\text{-}mid1}$ (ft amsl)	Elevation at Bottom of Layer at t_1, $z_{i\text{-}bott1}$ (ft amsl)	Thickness of Layer at t_1, H (ft)	Height above liner (ft)	Effective Stress at Midpoint of Layer at t_1, $\sigma'_{i\text{-}mid1}$ (psf)	Effective Stress at Bottom of Layer at t_1, $\sigma'_{i\text{-}bott1}$ (psf)	Void Ratio at t_0, e_0	Void Ratio at t_1, e_1	Secondary Compression Index, C_α	Change in Void Ratio due to 1000 years of Creep, Δe	Final Void Ratio After 1,000 years, e_{final}	Settlement due to 1000 years of Creep, δ_{creep} (ft)

ATTACHMENT F.3

SEISMIC SETTLEMENT CALCULATIONS

Notes

t_0 corresponds to beginning of final cover placement — Assumes 99% of consolidation due to existing stress conditions has taken place

t_1 corresponds to dewatering of the tailings to a level 5 feet above the liner

t_2 corresponds to completion of dewatering

SOIL PROPERTIES

TAILINGS

Value	Parameter	Source
Specific Gravity, G_s		
2.70	Specific gravity of tailing sands, $G_{s\text{-}TSand}$	Based on testing performed on other uranium tailings and presented in Keshian and Rager (1988)
2.80	Specific gravity of tailing sand-slimes, $G_{s\text{-}TS\text{-}S}$	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
2.86	Specific gravity of tailing slimes, $G_{s\text{-}TSlime}$	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
Fines Content		
18%	Fines content of tailings sands (%)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
47%	Fines content of tailings sand-slimes (%)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
71%	Fines content of tailings slimes (%)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
Dry Unit Weight, γ_d		
97	In-situ dry unit weight of tailings sands at t_0, $\gamma_{d0\text{-}Tsand}$ (pcf)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
88	In-situ dry unit weight of tailings sand-slimes at t_0, $\gamma_{d0\text{-}TS\text{-}S}$ (pcf)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
78	In-situ dry unit weight of tailings slimes at t_0, $\gamma_{d0\text{-}Tslime}$ (pcf)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
Saturated Unit Weight, γ_{sat}		
123	In-situ saturated unit weight of tailings sands at t_0, $\gamma_{sat0\text{-}Tsand}$ (pcf)	Calculated
119	In-situ saturated unit weight of tailings sand-slimes at t_0, $\gamma_{sat0\text{-}TS\text{-}S}$ (pcf)	Calculated
113	In-situ saturated unit weight of tailings slimes at t_0, $\gamma_{sat0\text{-}Tslime}$ (pcf)	Calculated
Moist Unit Weight, γ_m		
103	Moist unit weight of tailings sands, $\gamma_{m\text{-}Tsand}$ (pcf)	Calculated, assuming long-term water content from laboratory testing (Tailings Data Analysis Report. MWH, 2015b)
93	Moist unit weight of tailings sand-slimes, $\gamma_{m\text{-}TS\text{-}S}$ (pcf)	Calculated, assuming long-term water content from laboratory testing (Tailings Data Analysis Report. MWH, 2015b)
83	Moist unit weight of tailings slimes, $\gamma_{m\text{-}Tslime}$ (pcf)	Calculated, assuming long-term water content from laboratory testing (Tailings Data Analysis Report. MWH, 2015b)
Void Ratio, e		
0.74	Void ratio of tailing sands at t_0, $e_{0\text{-}TSand}$	Calculated
0.99	Void ratio of tailing sand-slimes at t_0, $e_{0\text{-}TS\text{-}S}$	Calculated
1.29	Void ratio of tailing slimes at t_0, $e_{0\text{-}TSlime}$	Calculated
Saturated Water Content, w_{Sat}		
27%	Saturated water content of tailings sands at t_0, $w_{sat0\text{-}TSand}$ (%)	Calculated
35%	Saturated water content of tailings sand-slimes at t_0, $w_{sat0\text{-}TS\text{-}S}$ (%)	Calculated
45%	Saturated water content of tailings slimes at t_0, $w_{sat0\text{-}TSlime}$ (%)	Calculated
Water Content of Moist Tailings, $w_{m\text{-}T}$		
6%	Water content of moist tailings sands, $w_{m\text{-}TSand}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
6%	Water content of moist tailings sand-slimes, $w_{m\text{-}TS\text{-}S}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
6%	Water content of moist tailings slimes, $w_{m\text{-}TSlime}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
Plasticity Index, PI		
0	Plasticity index of tailings sands, PI_{TSand}	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
10	Plasticity index of tailings sand-slimes, $PI_{TS\text{-}S}$	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
16	Plasticity index of tailings slimes, PI_{TSlime}	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
Seismic Settlement Coefficients		
2.2	Coefficient "a" of Unsaturated Sand Tailings	From Stewart, et al (2004), page 86, Figure 6.5
5.0	Coefficient "a" of Saturated Sand Tailings	From Stewart, et al (2004), page 86, Figure 6.5
2.0	Coefficient "a" of Sand-Slime Tailings	From Stewart, et al (2004), page 89, Figure 6.7
2.0	Coefficient "a" of Slime Tailings	From Stewart, et al (2004), page 89, Figure 6.7
1.00	Coefficient "b" of Sand Tailings	From Stewart, et al (2004), page 86, Figure 6.5
0.65	Coefficient "b" of Sand-Slime Tailings	From Stewart, et al (2004), page 89, Figure 6.7
0.65	Coefficient "b" of Slime Tailings	From Stewart, et al (2004), page 89, Figure 6.7
0.01%	Strain threshold value of Sand Tailings, γtv	From Stewart, et al (2004), page 86, Figure 6.5
0.03%	Strain threshold value of Sand-Slime Tailings, γtv	From Stewart, et al (2004), page 89, Figure 6.7
0.03%	Strain threshold value of Slime Tailings, γtv	From Stewart, et al (2004), page 89, Figure 6.7
0.36	Coefficient "R" of Sand Tailings	From Stewart, et al (2004), page 86, for soils with non-plastic fines
0.34	Coefficient "R" of Sand-Slime Tailings	From Stewart, et al (2004), page 89, for soils with medium plasticity fines
0.34	Coefficient "R" of Slime Tailings	From Stewart, et al (2004), page 89, for soils with medium plasticity fines

Other

5.0	Height of water table above liner at t_1, H_{sat-1} (ft)	Assumed for end of active maintenance
0.0	Height of water table above liner at t_2, H_{sat-2} (ft)	
6.0%	Long-term moisture content of tailings, $w_{tailings}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
508	Shear Wave Velocity of Tailings, V_s (ft/sec)	Conservatively assumed to be the average of the shear wave velocities measured in Cell 2 tailings

COVER SOIL

Specific Gravity, G_s

2.61	Specific gravity of topsoil, $G_{s\text{-Topsoil}}$	From Attachment H - Radon Emanation Modeling including with this submittal
2.62	Specific gravity of rock mulch, $G_{s\text{-mulch}}$	From Attachment H - Radon Emanation Modeling including with this submittal
2.63	Specific gravity of cover soil, $G_{s\text{-cover}}$	From Attachment H - Radon Emanation Modeling including with this submittal

Unit Weight, γ

118.0	Maximum dry unit weight of cover soil $\gamma_{cover\text{-}max}$ (pcf)	Average calculated from laboratory testing results (UWM, 2012)
100.7	Moist unit weight of cover soil at 80% relative compaction, $\gamma_{cover80}$ (pcf)	Calculated
107.0	Moist unit weight of cover soil at 85% relative compaction, $\gamma_{cover85}$ (pcf)	Calculated
119.6	Moist unit weight of cover soil at 95% relative compaction, $\gamma_{cover95}$ (pcf)	Calculated
100	Dry unit weight of topsoil layer at 85% relative compaction, $\gamma_{topsoil5}$ (pcf)	From Attachment H - Radon Emanation Modeling including with this submittal
105	Moist unit weight of topsoil layer at 85% relative compaction, $\gamma_{topsoil5}$ (pcf)	Calculated
106	Dry unit weight of rock mulch layer at 85% relative compaction, $\gamma_{mulch85}$ (pcf)	Calculated
110	Moist unit weight of rock mulch layer at 85% relative compaction, $\gamma_{mulch85}$ (pcf)	From Attachment H - Radon Emanation Modeling including with this submittal

Void Ratio, e

0.74	Void Ratio of cover soil at 80% relative compaction, $e_{cover80}$	Calculated
0.64	Void Ratio of cover soil at 85% relative compaction, $e_{cover85}$	Calculated
0.46	Void Ratio of cover soil at 95% relative compaction, $e_{cover95}$	Calculated
0.61	Void Ratio of topsoil at 85% relative compaction, $e_{topsoil85}$	Calculated from porosity presented in Attachment H - Radon Emanation Modeling including with this submittal
0.54	Void Ratio of rock mulch at 85% relative compaction, $e_{mulch85}$	Calculated from porosity presented in Attachment H - Radon Emanation Modeling including with this submittal

Seismic Settlement Coefficients

1.2	Coefficient "a" of Erosion Protection/Topsoil Cover	From Stewart, et al (2004), page 88, Figure 6.6
2.0	Coefficient "a" of General Cover Soil	From Stewart, et al (2004), page 89, Figure 6.7
0.65	Coefficient "a" of High-Compaction Layer	From Stewart, et al (2004), page 89, Figure 6.7
0.80	Coefficient "b" of Erosion Protection/Topsoil Cover	From Stewart, et al (2004), page 88, Figure 6.6
0.65	Coefficient "b" of General Cover Soil	From Stewart, et al (2004), page 89, Figure 6.7
0.75	Coefficient "b" of High-Compaction Layer	From Stewart, et al (2004), page 89, Figure 6.7
0.04%	Strain threshold value of Erosion Protection/Topsoil Cover, γtv	From Stewart, et al (2004), page 88, Figure 6.6
0.03%	Strain threshold value of General Cover Soil, γtv	From Stewart, et al (2004), page 89, Figure 6.7
0.02%	Strain threshold value of High-Compaction Layer, γtv	From Stewart, et al (2004), page 89, Figure 6.7
0.32	Coefficient "R" of Erosion Protection/Topsoil Cover	From Stewart, et al (2004), page 88, for soils with low plasticity fines
0.34	Coefficient "R" of General Cover Soil	From Stewart, et al (2004), page 89, for soils with medium plasticity fines
0.34	Coefficient "R" of High-Compaction Layer	From Stewart, et al (2004), page 89, for soils with medium plasticity fines

Other

6.7%	Long-term moisture content of cover soil, w_{cover} (%)	Estimated based on measured 15bar water content. (UWM, 2012)
5.2%	Long-term moisture content of topsoil, $w_{topsoil}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
4.0%	Long-term moisture content of rock mulch, $w_{rockmulch}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
0.14	Compression index of cover soil, $C_{c\text{-cover}}$	Calculated from empirical equation presented in Holtz and Kovacs, 1981. Page 341. $C_c = 0.30*(e_0-0.27)$
51%	Fines content of cover soil (%)	Mean value from laboratory analyses presented in previous response to interrogatories (EFRI, 2012)
11	Plasticity Index of cover soil, PI	Weighted Average from 2010 and 2012 laboratory testing (laboratory results presented in EFRI, 2012)
508	Shear Wave Velocity of Cover Soil, V_s (ft/sec)	Conservatively assumed to be the average of the shear wave velocities measured in Cell 2 tailings

SEISMIC PARAMETERS

0.15	Maximum horizontal acceleration at the ground surface, a_{max}/g	From Probabilistic Seismic Hazard Analysis (MWH, 2015a)
5.5	Magnitude of Design Event, M	From Probabilistic Seismic Hazard Analysis (MWH, 2015a)
20	Site-Source Distance, r (km)	From Probabilistic Seismic Hazard Analysis (MWH, 2015a)
1.00	Stress reduction factor, r_d	Conservatively assumed.
7.51	Equiv. Number of Uniform Strain Cycles, N	Calculated from Stewart, et al (2004), Equation 6.11, page 79, S parameter =0 since shallow soil and rock underlie the tailings (<20m) below tailings
594	Average shear wave velocity for cover, Vs (ft/s)	Conservatively estimated as upper bound average Vs for tailings in Cell 2 in October 2013 (Tailings Data Analysis Report. MWH, 2015b)
495	Average shear wave velocity for tailings (3' - 9.4'), Vs (ft/s)	Conservatively estimated as average Vs over depth range for tailings in Cell 2 in October 2013 (Tailings Data Analysis Report. MWH, 2015b)
460	Average shear wave velocity for tailings (9.4' - 14.4'), Vs (ft/s)	Conservatively estimated as average Vs over depth range for tailings in Cell 2 in October 2013 (Tailings Data Analysis Report. MWH, 2015b)
500	Average shear wave velocity for tailings (14.4' - 19.6'), Vs (ft/s)	Conservatively estimated as average Vs over depth range for tailings in Cell 2 in October 2013 (Tailings Data Analysis Report. MWH, 2015b)
538	Average shear wave velocity for tailings (19.6' - 24.7'), Vs (ft/s)	Conservatively estimated as average Vs over depth range for tailings in Cell 2 in October 2013 (Tailings Data Analysis Report. MWH, 2015b)
594	Average shear wave velocity for tailings (24.7' - liner), Vs (ft/s)	Conservatively estimated as average Vs over depth range for tailings in Cell 2 in October 2013 (Tailings Data Analysis Report. MWH, 2015b)

MISCELLANEOUS PARAMETERS

62.4	Unit Weight of Water, γ_w	
82.4	Atmospheric Pressure, P_a (kPa)	Calculated assuming elev=5600' amsl. http://www.engineeringtoolbox.com/air-altitude-pressure-d_462.html
1722.0	Atmospheric Pressure, P_a (psf)	Unit conversion calculation

Seismic Settlement Analysis - Stewart et al (2004)

TOTAL SEISMIC SETTLEMENT (FT): 0.347

Depth at t_1, z_1 m	Shear Wave Velocity, V_s (ft/sec)	Soil Density, ρ (tcf)	Maximum Shear Strain Modulus, G_{max} tsf	P = γ_{eff}*(G_{eff}/G_{max}) tsf	Plasticity Index, PI	g_1	g_2	Shear Strain, γ (%)	a	b	Threshhold Shear Strain, γ_{tv} (%)	Volumetric Strain at 15 Cycles, ε_{c-15} (%)	R	c	C_N	Volumetric Strain for Design Event, ε_v (%)	Incremental Consolidation (ft)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 2W2

Data File: 13-52106_SP2W2-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Dat

Legend:
- Tailings Sands
- Tailings Sand-Slimes
- Tailings Slimes
- Interim Cover
- Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Parameter
5613.10	Water surface elevation during CPT investigation (ft a
5607.57	Water surface elevation at t_0 (ft amsl)
5598.51	Water surface elevation at t_1 (ft amsl)
5593.51	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Earth
7.51	Equiv. Number of Uniform Strain Cycles, N
5615.85	Ground Surface Elevation at time of CPT (ft amsl)
5625.87	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after plac
3.50	Thickness of Water Storage/Rooting Zone (ft)
4.00	Thickness of High Compaction Layer (ft)
2.02	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1111.60	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5593.51	Elevation of bottom of tailings (liner) (ft amsl)

- Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Parameter
5613.80	Water surface elevation during CPT investigation (ft
5607.44	Water surface elevation at t_0 (ft amsl)
5597.74	Water surface elevation at t_1 (ft amsl)
5592.74	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Ear
7.51	Equiv. Number of Uniform Strain Cycles, N

Value	Parameter
5615.72	Ground Surface Elevation at time of CPT (ft amsl)
5626.27	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after plac
3.50	Thickness of Water Storage/Rooting Zone Layer (ft)
4.00	Thickness of High Compaction Layer (ft)
2.55	Thickness of Random/Platform Fill on top of existing interim cover (ft)
1164.98	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5592.74	Elevation of bottom of tailings (liner) (ft amsl)

Extra layer added to analyze seismic settlement of tailings below the bottom of CPT investigation.

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 2W4-C

Data File: 13-52106_SP2W4-C-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Da

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Parameter
5611.20	Water surface elevation during CPT investigation (ft amsl)
5607.96	Water surface elevation at t_0 (ft amsl)
5593.50	Water surface elevation at t_1 (ft amsl)
5588.50	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Earthq
7.51	Equiv. Number of Uniform Strain Cycles, N
5616.24	Ground Surface Elevation at time of CPT (ft amsl)
5626.19	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pla
3.50	Thickness of Water Storage/Rooting Zone (ft)
4.00	Thickness of High Compaction Layer (ft)
1.95	Thickness of Random/Platform Fill on top of existing interim cover (ft)
1104.55	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5588.50	Elevation of bottom of tailings (liner) (ft amsl)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 2W4-C

Data File: 13-52106_SP2W4-C-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Da

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)

Parameter	Value
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69

Youd, et al (2001)

Parameter	Value
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Description
5611.20	Water surface elevation during CPT investigation (ft a
5607.96	Water surface elevation at t_0 (ft amsl)
5593.50	Water surface elevation at t_1 (ft amsl)
5588.50	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ratio, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Earth
7.51	Equiv. Number of Uniform Strain Cycles, N
5616.24	Ground Surface Elevation at time of CPT (ft amsl)
5626.19	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pla
3.50	Thickness of Water Storage/Rooting Zone (ft)
4.00	Thickness of High Compaction Layer (ft)
1.95	Thickness of Random/Platform Fill on top of existing interim cover (ft)
1104.55	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5588.50	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Elev. At Bottom of Layer	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Total Stress at Bottom of Layer	Total Stress at Midpoint of Layer	Equil Pore Pressure at Bottom of Layer	Equil Pore Pressure Midpoint of Layer (tsf)	Effective Stress at Bottom of Layer	Effective Stress at Midpoint of Layer	Midpoint Depth at t_1, z_1	Shear Wave Velocity, V_s	Soil Density, ρ (tcf)	Max Shear Strain Modulus, G_{max} (tsf)	P = γ_{eff}*(G_{eff}/G_{max}) (tsf)	Plasticity Index, PI	g_1	g_2	Shear Strain, γ (%)	a	b	Threshold Shear Strain, γ_{tv} (%)	Volumetric Strain at 15 Cycles, ε_{c-15} (%)	R	c	C_N	Volumetric Strain for Design Event, ε_v (%)	Incremental Consolidation (ft)

Extra layer added to analyze seismic settlement of tailings below the bottom of CPT investigation.

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 2W6-S

Data File: 13-52106_SP2W6-S-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Da

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)
- Max. Horiz. Acceleration, Amax/g: 0.15
- Earthquake Moment Magnitude, M: 5.5
- Magnitude Scaling Factor, MSF: 1.69

Youd, et al (2001)
- Max. Horiz. Acceleration, Amax/g: 0.15
- Earthquake Moment Magnitude, M: 5.5
- Magnitude Scaling Factor, MSF: 2.21

Value	Parameter
5604.40	Water surface elevation during CPT investigation (ft amsl)
5604.40	Water surface elevation at t_1 (ft amsl)
5588.59	Water surface elevation at t_2 (ft amsl)
5583.59	Water surface elevation at t_3 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Ear
7.51	Equiv. Number of Uniform Strain Cycles, N
5615.85	Ground Surface Elevation at time of CPT (ft amsl)
5625.41	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pla
3.50	Thickness of Water Storage/Rooting Zone (ft)
4.00	Thickness of High Compaction Layer (ft)
1.56	Thickness of Random/Platform Fill on top of existing interim cover (ft)
1065.26	Additional Stress due to Final Cover Placement, $\Delta\sigma_{vc}$ (psf)
5583.59	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Elev. At Bottom of Layer	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Total Stress at Bottom of Layer	Total Stress at Midpoint of Layer	Equil Pore Pressure at Bottom of Layer (tsf)	Equil Pore Pressure at Midpoint of Layer (tsf)	Effective Stress at Bottom of Layer	Effective Stress at Midpoint of Layer	Midpoint Depth at t_1, z_1	Shear Wave Velocity, V_s	Soil Density, ρ	Max Shear Strain Modulus, G_{max} (tsf)	P = γ_{eff}*(G_{eff}/G_{max})	Plasticity Index, PI	g_1	g_2	Shear Strain, γ (%)	a	b	Threshold Shear Strain, γ_{tv} (%)	Volumetric Strain at 15 Cycles, $\varepsilon_{c,15}$ (%)	R	c	C_N	Volumetric Strain for Design Event, ε_v (%)	Incremental Consolidation (ft)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 2W6-S

Data File: 13-52106_SP2W6-S-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3 Field Data\2013 Field Investigation\Conetec Da

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Parameter
5604.40	Water surface elevation during CPT investigation (ft amsl)
5604.40	Water surface elevation at t_0 (ft amsl)
5588.59	Water surface elevation at t_1 (ft amsl)
5583.59	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ratio, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Ear
7.51	Equiv. Number of Uniform Strain Cycles, N
5615.85	Ground Surface Elevation at time of CPT (ft amsl)
5625.41	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pla
3.50	Thickness of Water Storage/Rooting Zone (ft)
4.00	Thickness of High Compaction Layer (ft)
1.56	Thickness of Random/Platform Fill on top of existing interim cover (ft)
1065.26	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5583.59	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Elev. At Bottom of Layer	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Total Stress at Bottom of Layer	Total Stress at Midpoint of Layer	Equil Pore Pressure at Bottom of Layer	Equil Pore Pressure Midpoint of Layer (tsf)	Effective Stress at Bottom of Layer	Effective Stress at Midpoint of Layer	Midpoint Depth at t_1, z_1	Shear Wave Velocity, V_s	Soil Density, ρ (tcf)	Max Shear Strain Modulus, G_{max} (tsf)	P = γ_{eff}*(G_{eff}/G_{max}) (tsf)	Plasticity Index, PI	g_1	g_2	Shear Strain, γ (%)	a	b	Threshold Shear Strain, γ_{tv} (%)	Volumetric Strain at 15 Cycles, ε_{c-15} (%)	R	c	C_N	Volumetric Strain for Design Event, ε_v (%)	Incremental Consolidation (ft)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 2W7-C

Data File: 13-52106_SP2W7-C-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Da

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Parameter
5613.10	Water surface elevation during CPT investigation (ft amsl)
5611.32	Water surface elevation at t_0 (ft amsl)
5595.40	Water surface elevation at t_1 (ft amsl)
5590.40	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ratio, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Ear
7.51	Equiv. Number of Uniform Strain Cycles, N
5619.60	Ground Surface Elevation at time of CPT (ft amsl)
5626.65	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pl
3.50	Thickness of Water Storage/Rooting Zone (ft)
4.00	Thickness of High Compaction Layer (ft)
-0.95	Thickness of Random/Platform Fill on top of existing interim cover (ft)
812.44	Additional Stress due to Final Cover Placement, $\Delta\sigma_{vc}$ (psf)
5590.40	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Elev. At Bottom of Layer	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Total Stress at Bottom of Layer	Total Stress at Midpoint of Layer	Equil Pore Pressure at Bottom of Layer	Equil Pore Pressure at Midpoint of Layer (tsf)	Effective Stress at Bottom of Layer	Effective Stress at Midpoint of Layer	Midpoint Depth at t_2, z_i	Shear Wave Velocity, V_s	Soil Density, ρ (tcf)	Max Shear Strain Modulus, G_{max} (tsf)	P = γ_{eff}*(G_{eff}/G_{max}) (tsf)	Plasticity Index, PI	g_1	g_2	Shear Strain, γ (%)	a	b	Threshold Shear Strain, γ_{tv} (%)	Volumetric Strain at 15 Cycles, $\varepsilon_{c,15}$ (%)	R	c	C_N	Volumetric Strain for Design Event, ε_v (%)	Incremental Consolidation (ft)

Extra layer added to analyze seismic settlement of tailings below the bottom of CPT investigation.

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 2E1

Data File: 13-52106_SP2E1-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Dat

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Parameter
5613.10	Water surface elevation during CPT investigation (ft a
5611.67	Water surface elevation at t_0 (ft amsl)
5595.46	Water surface elevation at t_1 (ft amsl)
5590.46	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Earth
7.51	Equiv. Number of Uniform Strain Cycles, N
5619.95	Ground Surface Elevation at time of CPT (ft amsl)
5630.46	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after place
3.50	Thickness of Water Storage/Rooting Zone (ft)
4.00	Thickness of High Compaction Layer (ft)
2.51	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1160.95	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5590.46	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Elev. At Bottom of Layer	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Total Stress at Bottom of Layer	Total Stress at Midpoint of Layer	Equil Pore Pressure at Bottom of Layer	Equil Pore Pressure at Midpoint of Layer (tsf)	Effective Stress at Bottom of Layer	Effective Stress at Midpoint of Layer	Midpoint Depth at t_1, z_1	Shear Wave Velocity, V_s	Soil Density, ρ (tcf)	Max Shear Strain Modulus, G_{max} (tsf)	P = γ_{eff}*(G_{eff}/G_{max}) (tsf)	Plasticity Index, PI	g_1	g_2	Shear Strain, γ (%)	a	b	Threshold Shear Strain, γ_{tv} (%)	Volumetric Strain at 15 Cycles, ε_{c-15} (%)	R	c	C_N	Volumetric Strain for Design Event, ε_v (%)	Incremental Consolidation (ft)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 2E1

Data File: 13-52106_SP2E1-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Dat

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

5613.10	Water surface elevation during CPT investigation (ft a
5611.67	Water surface elevation at t_0 (ft amsl)
5595.46	Water surface elevation at t_1 (ft amsl)
5590.46	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Earth
7.51	Equiv. Number of Uniform Strain Cycles, N

5619.95	Ground Surface Elevation at time of CPT (ft amsl)
5630.46	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after place
3.50	Thickness of Water Storage/Rooting Zone (ft)
4.00	Thickness of High Compaction Layer (ft)
2.51	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1160.95	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5590.46	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Elev. At Bottom of Layer	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Total Stress at Bottom of Layer	Total Stress at Midpoint of Layer	Equil Pore Pressure at Bottom of Layer	Equil Pore Pressure at Midpoint of Layer (tsf)	Effective Stress at Bottom of Layer	Effective Stress at Midpoint of Layer	Midpoint Depth at t_1, z_1	Shear Wave Velocity, V_s	Soil Density, ρ (tcf)	Max Shear Strain Modulus, G_{max} (tsf)	P = γ_{eff}*(G_{eff}/G_{max}) (tsf)	Plasticity Index, PI	g_1	g_2	Shear Strain, γ (%)	a	b	Threshhold Shear Strain, γ_{tv} (%)	Volumetric Strain at 15 Cycles, ε_{c-15} (%)	R	c	C_N	Volumetric Strain for Design Event, ε_v (%)	Incremental Consolidation (ft)

Extra layer added to analyze seismic settlement of tailings below the bottom of CPT investigation.

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 3-1S

Data File: 13-52106_SP3-1S-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Da

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Description
5608.00	Water surface elevation during CPT investigation (ft amsl)
5604.28	Water surface elevation at t_0 (ft amsl)
5595.59	Water surface elevation at t_1 (ft amsl)
5590.59	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Eart
7.51	Equiv. Number of Uniform Strain Cycles, N
5612.56	Ground Surface Elevation at time of CPT (ft amsl)
5620.47	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pla
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
0.41	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
887.10	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5590.59	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Elev. At Bottom of Layer	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Total Stress at Bottom of Layer	Total Stress at Midpoint of Layer	Equil Pore Pressure at Bottom of Layer	Equil Pore Pressure at Midpoint of Layer (tsf)	Effective Stress at Bottom of Layer	Effective Stress at Midpoint of Layer	Midpoint Depth at t_1, z_1	Shear Wave Velocity, V_s	Soil Density, ρ (tcf)	Max Shear Strain Modulus, G_{max} (tsf)	$P = \gamma_{eff}*(G_{eff}/G_{max})$ (tsf)	Plasticity Index, PI	g_1	g_2	Shear Strain, γ (%)	a	b	Threshhold Shear Strain, γ_{tv} (%)	Volumetric Strain at 15 Cycles, ε_{c-15} (%)	R	c	C_N	Volumetric Strain for Design Event, ε_v (%)	Incremental Consolidation (ft)

Seismic Settlement Analysis - Stewart et al (2004)

TOTAL SEISMIC SETTLEMENT (FT): 0.235

Depth at time of CPT (ft)	Depth at t_1, z_1 (m)	Shear Wave Velocity, V_s (ft/sec)	Soil Density, ρ (tcf)	Maximum Shear Strain Modulus, G_{max} (tsf)	$P = \gamma_{eff}*(G_{eff}/G_{max})$ (tsf)	Plasticity Index, PI	g_1	g_2	Shear Strain, γ (%)	a	b	Threshhold Shear Strain, γ_{tv} (%)	Volumetric Strain at 15 Cycles, ε_{c-15} (%)	R	c	C_N	Volumetric Strain for Design Event, ε_v (%)	Incremental Consolidation (ft)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 3-1S

Data File: 13-52106_SP3-1S-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3 Field Data\2013 Field Investigation\Conetec Dat

Legend:
- Tailings Sands
- Tailings Sand-Slimes
- Tailings Slimes
- Interim Cover
- Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69

Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Parameter
5608.00	Water surface elevation during CPT investigation (ft
5604.28	Water surface elevation at t_0 (ft amsl)
5595.59	Water surface elevation at t_1 (ft amsl)
5590.59	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Eart
7.51	Equiv. Number of Uniform Strain Cycles, N

Value	Parameter
5612.56	Ground Surface Elevation at time of CPT (ft amsl)
5620.47	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pla
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
0.41	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
887.10	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5590.59	Elevation of bottom of tailings (liner) (ft amsl)

Extra layer added to analyze seismic settlement of tailings below the bottom of CPT investigation.

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 3-2C

Data File:	13-52106_SP3-2C-BSC-CPT	**Idriss and Boulanger (2008)**			
Location:	White Mesa 2013 CPT Investigation	Max. Horiz. Acceleration, Amax/g:	0.15		
..\..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Da		Earthquake Moment Magnitude, M:	5.5		
	Tailings Sands	Magnitude Scaling Factor, MSF:	1.69		
	Tailings Sand-Slimes	**Youd, et al (2001)**			
	Tailings Slimes	Max. Horiz. Acceleration, Amax/g:	0.15		
	Interim Cover	Earthquake Moment Magnitude, M:	5.5		
	Cells Requiring User Input/Manipulation	Magnitude Scaling Factor, MSF:	2.21		

Value	Description
5605.30	Water surface elevation during CPT investigation (ft amsl)
5602.54	Water surface elevation at t_0 (ft amsl)
5591.64	Water surface elevation at t_1 (ft amsl)
5586.64	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Earthquake
7.51	Equiv. Number of Uniform Strain Cycles, N
5610.82	Ground Surface Elevation at time of CPT (ft amsl)
5621.51	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after placement
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
3.19	Thickness of Random/Platform Fill on top of existing interim cover (ft)
1167.12	Additional Stress due to Final Cover Placement, $\Delta\sigma_{fc}$ (psf)
5586.64	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Bottom of Layer (ft)	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)	Pore Pressure at Bottom of Layer (tsf)	Equil Pore Pressure at Midpoint of Layer (tsf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)	Midpoint Depth at t_1, z_1	Shear Wave Velocity, V_s	Soil Density, ρ (tcf)	Max Shear Strain Modulus, G_{max} (tsf)	P = γ_{eff}*(G_{eff}/G_{max}) (tsf)	Plasticity Index, PI	g_1	g_2	Shear Strain, γ (%)	a	b	Threshold Shear Strain, γ_{tv} (%)	Volumetric Strain at 15 Cycles, ε_{c-15}	R	c	C_N	Volumetric Strain for Design Event, ε_v (%)	Incremental Consolidation (ft)

Seismic Settlement Analysis - Stewart et al (2004)

TOTAL SEISMIC SETTLEMENT (FT): 0.397

Depth at t_1, z_1 (m)	Shear Wave Velocity, V_s (ft/sec)	Soil Density, ρ (tcf)	Maximum Shear Strain Modulus, G_{max} (tsf)	P = γ_{eff}*(G_{eff}/G_{max}) (tsf)	Plasticity Index, PI	g_1	g_2	Shear Strain, γ (%)	a	b	Threshold Shear Strain, γ_{tv} (%)	Volumetric Strain at 15 Cycles, ε_{c-15}	R	c	C_N	Volumetric Strain for Design Event, ε_v (%)	Incremental Consolidation (ft)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 3-2C

Data File: 13-52106_SP3-2C-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Da

Legend
Tailings Sands
Tailings Sand-Slimes
Tailings Slimes
Interim Cover
Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69

Youd, et al (2001)		
Max. Horiz. Acceleration, Amax/g:	0.15	
Earthquake Moment Magnitude, M:	5.5	
Magnitude Scaling Factor, MSF:	2.21	2.21

Value	Parameter
5605.30	Water surface elevation during CPT investigation (ft
5602.54	Water surface elevation at t_0 (ft amsl)
5591.64	Water surface elevation at t_1 (ft amsl)
5586.64	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Eart
7.51	Equiv. Number of Uniform Strain Cycles, N

Value	Parameter
5610.82	Ground Surface Elevation at time of CPT (ft amsl)
5621.51	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after plac
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
3.19	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1167.12	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5586.64	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)		Elev. At Midpoint of Layer (ft)	Bottom of Layer (ft)	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)	Pore Pressure at Bottom of Layer	Equil Pore Pressure at Midpoint of Layer (tsf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)	Midpoint Depth at t_1, z_1	Shear Wave Velocity, V_s	Soil Density, ρ (tcf)	Max Shear Strain Modulus, G_{max} (tsf)	P = γ_{eff}*(G_{eff}/G_{max}) (tsf)	Plasticity Index, PI	g_1	g_2	Shear Strain, γ (%)	a	b	Threshhold Shear Strain, γ_{tv} (%)	Volumetric Strain at 15 Cycles, ε_{c-}	R	c	C_N	Volumetric Strain for Design Event, ε_v (%)	Incremental Consolidation (ft)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 3-3S

Data File: 13-52106_SP3-3S-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Dat

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

5605.60	Water surface elevation during CPT investigation (ft
5601.35	Water surface elevation at t_0 (ft amsl)
5582.14	Water surface elevation at t_1 (ft amsl)
5577.14	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Eart
7.51	Equiv. Number of Uniform Strain Cycles, N

5609.63	Ground Surface Elevation at time of CPT (ft amsl)
5620.49	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pla
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
3.36	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1184.24	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5577.14	Elevation of bottom of tailings (liner) (ft amsl)

Extra layer added to analyze seismic settlement of tailings below the bottom of CPT investigation.

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 3-4N

Data File: 13-52106_SP3-4N-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3 Field Data\2013 Field Investigation\Conetec Dat

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Parameter
5606.00	Water surface elevation during CPT investigation (ft
5600.42	Water surface elevation at t_0 (ft amsl)
5583.71	Water surface elevation at t_1 (ft amsl)
5578.71	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Eart
7.51	Equiv. Number of Uniform Strain Cycles, N
5608.70	Ground Surface Elevation at time of CPT (ft amsl)
5623.35	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pl
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
7.15	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1565.99	Additional Stress due to Final Cover Placement, $\Delta\sigma_{fc}$ (psf)
5578.71	Elevation of bottom of tailings (liner) (ft amsl)

2013 CPT Data from ConeTec / CPT Data Interpretations

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 3-4N

Data File: 13-52106_SP3-4N-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3 Field Data\2013 Field Investigation\Conetec Dat

Legend:
- Tailings Sands
- Tailings Sand-Slimes
- Tailings Slimes
- Interim Cover
- Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69

Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Parameter
5606.00	Water surface elevation during CPT investigation (ft
5600.42	Water surface elevation at t_0 (ft amsl)
5583.71	Water surface elevation at t_1 (ft amsl)
5578.71	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Eart
7.51	Equiv. Number of Uniform Strain Cycles, N

Value	Parameter
5608.70	Ground Surface Elevation at time of CPT (ft amsl)
5623.35	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pla
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
7.15	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1565.99	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5578.71	Elevation of bottom of tailings (liner) (ft amsl)

Extra layer added to analyze seismic settlement of tailings below the bottom of CPT investigation.

Energy Fuels Resources (USA) Inc.
White Mesa Mill
Seismic Settlement Analyses

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 3-6N

Data File: 13-52106_SP3-6N-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Da

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Parameter
5604.20	Water surface elevation during CPT investigation (ft amsl)
5599.16	Water surface elevation at t_0 (ft amsl)
5590.44	Water surface elevation at t_1 (ft amsl)
5585.44	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Earthquake
7.51	Equiv. Number of Uniform Strain Cycles, N
5607.44	Ground Surface Elevation at time of CPT (ft amsl)
5623.62	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after plac
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
8.68	Thickness of Random/Platform Fill on top of existing interim cover (ft)
1720.10	Additional Stress due to Final Cover Placement, $\Delta\sigma_{fc}$ (psf)
5585.44	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Elev. At Bottom of Layer (ft)	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Total Stress at Bottom of Layer	Total Stress at Midpoint of Layer	Equil Pore Pressure at Bottom of Layer (tsf)	Equil Pore Pressure at Midpoint of Layer (tsf)	Effective Stress at Bottom of Layer	Effective Stress at Midpoint of Layer	Midpoint Depth at t_1, z_1	Shear Wave Velocity	Soil Density	Max Shear Strain Modulus, G_{max}	P = γ_{eff}*(G_{eff}/G_{max})	Plasticity Index, PI	g_1	g_2	Shear Strain, γ (%)	a	b	Threshold Shear Strain, γ_{tv} (%)	Volumetric Strain at 15 Cycles, ε_{c-15} (%)	R	c	C_N	Volumetric Strain for Design Event, ε_v (%)	Incremental Consolidation (ft)

Extra layer added to analyze seismic settlement of tailings below the bottom of CPT investigation.

ATTACHMENT F.4

LIQUEFACTION CALCULATIONS

Notes

t_0 corresponds to beginning of final cover placement — Assumes 99% of consolidation due to existing stress conditions has taken place

t_1 corresponds to dewatering of the tailings to a level 5 feet above the liner

t_2 corresponds to completion of dewatering

SOIL PROPERTIES

TAILINGS

Specific Gravity, G_s		
2.70	Specific gravity of tailing sands, $G_{s\text{-}TSand}$	Based on testing performed on other uranium tailings and presented in Keshian and Rager (1988)
2.80	Specific gravity of tailing sand-slimes, $G_{s\text{-}TS\text{-}S}$	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
2.86	Specific gravity of tailing slimes, $G_{s\text{-}TSlime}$	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
Fines Content		
18%	Fines content of tailings sands (%)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
47%	Fines content of tailings sand-slimes (%)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
71%	Fines content of tailings slimes (%)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
Dry Unit Weight, γ_d		
97	In-situ dry unit weight of tailings sands at t_0, $\gamma_{d0\text{-}Tsand}$ (pcf)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
88	In-situ dry unit weight of tailings sand-slimes at t_0, $\gamma_{d0\text{-}TS\text{-}S}$ (pcf)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
78	In-situ dry unit weight of tailings slimes at t_0, $\gamma_{d0\text{-}Tslime}$ (pcf)	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
Saturated Unit Weight, γ_{sat}		
123	In-situ saturated unit weight of tailings sands at t_0, $\gamma_{sat0\text{-}Tsand}$ (pcf)	Calculated
119	In-situ saturated unit weight of tailings sand-slimes at t_0, $\gamma_{sat0\text{-}TS\text{-}S}$ (pcf)	Calculated
113	In-situ saturated unit weight of tailings slimes at t_0, $\gamma_{sat0\text{-}Tslime}$ (pcf)	Calculated
Moist Unit Weight, γ_m		
103	Moist unit weight of tailings sands, $\gamma_{m\text{-}Tsand}$ (pcf)	Calculated, assuming long-term water content from laboratory testing (Tailings Data Analysis Report. MWH, 2015b)
93	Moist unit weight of tailings sand-slimes, $\gamma_{m\text{-}TS\text{-}S}$ (pcf)	Calculated, assuming long-term water content from laboratory testing (Tailings Data Analysis Report. MWH, 2015b)
83	Moist unit weight of tailings slimes, $\gamma_{m\text{-}Tslime}$ (pcf)	Calculated, assuming long-term water content from laboratory testing (Tailings Data Analysis Report. MWH, 2015b)
Void Ratio, e		
0.74	Void ratio of tailing sands at t_0, $e_{0\text{-}TSand}$	Calculated
0.99	Void ratio of tailing sand-slimes at t_0, $e_{0\text{-}TS\text{-}S}$	Calculated
1.29	Void ratio of tailing slimes at t_0, $e_{0\text{-}TSlime}$	Calculated
Saturated Water Content, w_{Sat}		
27%	Saturated water content of tailings sands at t_0, $w_{sat0\text{-}TSand}$ (%)	Calculated
35%	Saturated water content of tailings sand-slimes at t_0, $w_{sat0\text{-}TS\text{-}S}$ (%)	Calculated
45%	Saturated water content of tailings slimes at t_0, $w_{sat0\text{-}TSlime}$ (%)	Calculated
Water Content of Moist Tailings, $w_{m\text{-}T}$		
6%	Water content of moist tailings sands, $w_{m\text{-}TSand}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
6%	Water content of moist tailings sand-slimes, $w_{m\text{-}TS\text{-}S}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
6%	Water content of moist tailings slimes, $w_{m\text{-}TSlime}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
Plasticity Index, PI		
0	Plasticity index of tailings sands, PI_{TSand}	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
10	Plasticity index of tailings sand-slimes, $PI_{TS\text{-}S}$	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
16	Plasticity index of tailings slimes, PI_{TSlime}	Average value from lab testing of samples obtained on-site (Tailings Data Analysis Report. MWH, 2015b)
Seismic Settlement Coefficients		
2.2	Coefficient "a" of Unsaturated Sand Tailings	From Stewart, et al (2004), page 86, Figure 6.5
5.0	Coefficient "a" of Saturated Sand Tailings	From Stewart, et al (2004), page 86, Figure 6.5
2.0	Coefficient "a" of Sand-Slime Tailings	From Stewart, et al (2004), page 89, Figure 6.7
2.0	Coefficient "a" of Slime Tailings	From Stewart, et al (2004), page 89, Figure 6.7
1.00	Coefficient "b" of Sand Tailings	From Stewart, et al (2004), page 86, Figure 6.5
0.65	Coefficient "b" of Sand-Slime Tailings	From Stewart, et al (2004), page 89, Figure 6.7
0.65	Coefficient "b" of Slime Tailings	From Stewart, et al (2004), page 89, Figure 6.7
0.01%	Strain threshold value of Sand Tailings, γtv	From Stewart, et al (2004), page 86, Figure 6.5
0.03%	Strain threshold value of Sand-Slime Tailings, γtv	From Stewart, et al (2004), page 89, Figure 6.7
0.03%	Strain threshold value of Slime Tailings, γtv	From Stewart, et al (2004), page 89, Figure 6.7
0.36	Coefficient "R" of Sand Tailings	From Stewart, et al (2004), page 86, for soils with non-plastic fines
0.34	Coefficient "R" of Sand-Slime Tailings	From Stewart, et al (2004), page 89, for soils with medium plasticity fines
0.34	Coefficient "R" of Slime Tailings	From Stewart, et al (2004), page 89, for soils with medium plasticity fines

Other

5.0	Height of water table above liner at t_1, H_{sat-1} (ft)	Assumed for end of active maintenance
0.0	Height of water table above liner at t_2, H_{sat-2} (ft)	
6.0%	Long-term moisture content of tailings, $w_{tailings}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
508	Shear Wave Velocity of Tailings, V_s (ft/sec)	Conservatively assumed to be the average of the shear wave velocities measured in Cell 2 tailings

COVER SOIL

Specific Gravity, G_s

2.61	Specific gravity of topsoil, $G_{s\text{-Topsoil}}$	From Attachment H - Radon Emanation Modeling including with this submittal
2.62	Specific gravity of rock mulch, $G_{s\text{-mulch}}$	From Attachment H - Radon Emanation Modeling including with this submittal
2.63	Specific gravity of cover soil, $G_{s\text{-cover}}$	From Attachment H - Radon Emanation Modeling including with this submittal

Unit Weight, γ

118.0	Maximum dry unit weight of cover soil $\gamma_{cover\text{-}max}$ (pcf)	Average calculated from laboratory testing results (UWM, 2012)
100.7	Moist unit weight of cover soil at 80% relative compaction, $\gamma_{cover80}$ (pcf)	Calculated
107.0	Moist unit weight of cover soil at 85% relative compaction, $\gamma_{cover85}$ (pcf)	Calculated
119.6	Moist unit weight of cover soil at 95% relative compaction, $\gamma_{cover95}$ (pcf)	Calculated
100	Dry unit weight of topsoil layer at 85% relative compaction, $\gamma_{topsoil5}$ (pcf)	From Attachment H - Radon Emanation Modeling including with this submittal
105	Moist unit weight of topsoil layer at 85% relative compaction, $\gamma_{topsoil5}$ (pcf)	Calculated
106	Dry unit weight of rock mulch layer at 85% relative compaction, $\gamma_{mulch85}$ (pcf)	Calculated
110	Moist unit weight of rock mulch layer at 85% relative compaction, $\gamma_{mulch85}$ (pcf)	From Attachment H - Radon Emanation Modeling including with this submittal

Void Ratio, e

0.74	Void Ratio of cover soil at 80% relative compaction, $e_{cover80}$	Calculated
0.64	Void Ratio of cover soil at 85% relative compaction, $e_{cover85}$	Calculated
0.46	Void Ratio of cover soil at 95% relative compaction, $e_{cover95}$	Calculated
0.61	Void Ratio of topsoil at 85% relative compaction, $e_{topsoil85}$	Calculated from porosity presented in Attachment H - Radon Emanation Modeling including with this submittal
0.54	Void Ratio of rock mulch at 85% relative compaction, $e_{mulch85}$	Calculated from porosity presented in Attachment H - Radon Emanation Modeling including with this submittal

Seismic Settlement Coefficients

1.2	Coefficient "a" of Erosion Protection/Topsoil Cover	From Stewart, et al (2004), page 88, Figure 6.6
2.0	Coefficient "a" of General Cover Soil	From Stewart, et al (2004), page 89, Figure 6.7
0.65	Coefficient "a" of High-Compaction Layer	From Stewart, et al (2004), page 89, Figure 6.7
0.80	Coefficient "b" of Erosion Protection/Topsoil Cover	From Stewart, et al (2004), page 88, Figure 6.6
0.65	Coefficient "b" of General Cover Soil	From Stewart, et al (2004), page 89, Figure 6.7
0.75	Coefficient "b" of High-Compaction Layer	From Stewart, et al (2004), page 89, Figure 6.7
0.04%	Strain threshold value of Erosion Protection/Topsoil Cover, γtv	From Stewart, et al (2004), page 88, Figure 6.6
0.03%	Strain threshold value of General Cover Soil, γtv	From Stewart, et al (2004), page 89, Figure 6.7
0.02%	Strain threshold value of High-Compaction Layer, γtv	From Stewart, et al (2004), page 89, Figure 6.7
0.32	Coefficient "R" of Erosion Protection/Topsoil Cover	From Stewart, et al (2004), page 88, for soils with low plasticity fines
0.34	Coefficient "R" of General Cover Soil	From Stewart, et al (2004), page 89, for soils with medium plasticity fines
0.34	Coefficient "R" of High-Compaction Layer	From Stewart, et al (2004), page 89, for soils with medium plasticity fines

Other

6.7%	Long-term moisture content of cover soil, w_{cover} (%)	Estimated based on measured 15bar water content. (UWM, 2012)
5.2%	Long-term moisture content of topsoil, $w_{topsoil}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
4.0%	Long-term moisture content of rock mulch, $w_{rockmulch}$ (%)	From Attachment H - Radon Emanation Modeling including with this submittal
0.14	Compression index of cover soil, $C_{c\text{-cover}}$	Calculated from empirical equation presented in Holtz and Kovacs, 1981. Page 341. $C_c = 0.30*(e_0\text{-}0.27)$
51%	Fines content of cover soil (%)	Mean value from laboratory analyses presented in previous response to interrogatories (EFRI, 2012)
11	Plasticity Index of cover soil, PI	Weighted Average from 2010 and 2012 laboratory testing (laboratory results presented in EFRI, 2012)
508	Shear Wave Velocity of Cover Soil, V_s (ft/sec)	Conservatively assumed to be the average of the shear wave velocities measured in Cell 2 tailings

SEISMIC PARAMETERS

0.15	Maximum horizontal acceleration at the ground surface, a_{max}/g	From Probabilistic Seismic Hazard Analysis (MWH, 2015a)
5.5	Magnitude of Design Event, M	From Probabilistic Seismic Hazard Analysis (MWH, 2015a)
20	Site-Source Distance, r (km)	From Probabilistic Seismic Hazard Analysis (MWH, 2015a)
1.00	Stress reduction factor, r_d	Conservatively assumed.
7.51	Equiv. Number of Uniform Strain Cycles, N	Calculated from Stewart, et al (2004), Equation 6.11, page 79, S parameter =0 since shallow soil and rock underlie the tailings (<20m) below tailings
594	Average shear wave velocity for cover, Vs (ft/s)	Conservatively estimated as upper bound average Vs for tailings in Cell 2 in October 2013 (Tailings Data Analysis Report. MWH, 2015b)
495	Average shear wave velocity for tailings (3' - 9.4'), Vs (ft/s)	Conservatively estimated as average Vs over depth range for tailings in Cell 2 in October 2013 (Tailings Data Analysis Report. MWH, 2015b)
460	Average shear wave velocity for tailings (9.4' - 14.4'), Vs (ft/s)	Conservatively estimated as average Vs over depth range for tailings in Cell 2 in October 2013 (Tailings Data Analysis Report. MWH, 2015b)
500	Average shear wave velocity for tailings (14.4' - 19.6'), Vs (ft/s)	Conservatively estimated as average Vs over depth range for tailings in Cell 2 in October 2013 (Tailings Data Analysis Report. MWH, 2015b)
538	Average shear wave velocity for tailings (19.6' - 24.7'), Vs (ft/s)	Conservatively estimated as average Vs over depth range for tailings in Cell 2 in October 2013 (Tailings Data Analysis Report. MWH, 2015b)
594	Average shear wave velocity for tailings (24.7' - liner), Vs (ft/s)	Conservatively estimated as average Vs over depth range for tailings in Cell 2 in October 2013 (Tailings Data Analysis Report. MWH, 2015b)

MISCELLANEOUS PARAMETERS

62.4	Unit Weight of Water, γ_W	
82.4	Atmospheric Pressure, P_a (kPa)	Calculated assuming elev=5600' amsl. http://www.engineeringtoolbox.com/air-altitude-pressure-d_462.html
1722.0	Atmospheric Pressure, P_a (psf)	Unit conversion calculation

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 2W4-C

Data File: 13-52106_SP2W4-C-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Da

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Parameter
5611.20	Water surface elevation during CPT investigation (ft a
5607.96	Water surface elevation at t_0 (ft amsl)
5593.50	Water surface elevation at t_1 (ft amsl)
5588.50	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Earth
7.51	Equiv. Number of Uniform Strain Cycles, N
5616.24	Ground Surface Elevation at time of CPT (ft amsl)
5626.19	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pla
3.50	Thickness of Water Storage/Rooting Zone (ft)
4.00	Thickness of High Compaction Layer (ft)
1.95	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1104.55	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5588.50	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Bottom of Layer (ft)	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)	Pressure at Bottom of Layer (tsf)	Equil Pore Pressure at Midpoint of Layer (tsf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 2W5-C

Data File: 13-52106_SP2W5-C-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Da

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Description
5604.20	Water surface elevation during CPT investigation (ft
5604.20	Water surface elevation at t_0 (ft amsl)
5589.01	Water surface elevation at t_1 (ft amsl)
5584.01	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Ear
7.51	Equiv. Number of Uniform Strain Cycles, N
5615.86	Ground Surface Elevation at time of CPT (ft amsl)
5626.28	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pla
3.50	Thickness of Water Storage/Rooting Zone (ft)
4.00	Thickness of High Compaction Layer (ft)
2.42	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1151.89	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5584.01	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Bottom of Layer (ft)	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)	Pressure at Bottom of Layer (tsf)	Equil Pore Pressure at Midpoint of Layer (tsf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 2W6-S

Data File: 13-52106_SP2W6-S-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\.\6.2.3_Field Data\2013 Field Investigation\Conetec Da

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)
- Max. Horiz. Acceleration, Amax/g: 0.15
- Earthquake Moment Magnitude, M: 5.5
- Magnitude Scaling Factor, MSF: 1.69

Youd, et al (2001)
- Max. Horiz. Acceleration, Amax/g: 0.15
- Earthquake Moment Magnitude, M: 5.5
- Magnitude Scaling Factor, MSF: 2.21

Value	Parameter
5604.40	Water surface elevation during CPT investigation (f
5604.40	Water surface elevation at t_0 (ft amsl)
5588.59	Water surface elevation at t_1 (ft amsl)
5583.59	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Ear
7.51	Equiv. Number of Uniform Strain Cycles, N
5615.85	Ground Surface Elevation at time of CPT (ft amsl)
5625.41	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pl
3.50	Thickness of Water Storage/Rooting Zone (ft)
4.00	Thickness of High Compaction Layer (ft)
1.56	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1065.26	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5583.59	Elevation of bottom of tailings (liner) (ft amsl)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 2W6-S

Data File: 13-52106_SP2W6-S-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Da

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Description
5604.40	Water surface elevation during CPT investigation (f
5604.40	Water surface elevation at t_0 (ft amsl)
5588.59	Water surface elevation at t_1 (ft amsl)
5583.59	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Ear
7.51	Equiv. Number of Uniform Strain Cycles, N

Value	Description
5615.85	Ground Surface Elevation at time of CPT (ft amsl)
5625.41	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pl
3.50	Thickness of Water Storage/Rooting Zone (ft)
4.00	Thickness of High Compaction Layer (ft)
1.56	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1065.26	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5583.59	Elevation of bottom of tailings (liner) (ft amsl)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 2W7-C

Data File: 13-52106_SP2W7-C-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Da

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Parameter
5613.10	Water surface elevation during CPT investigation (ft
5611.32	Water surface elevation at t_0 (ft amsl)
5595.40	Water surface elevation at t_1 (ft amsl)
5590.40	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Ea
7.51	Equiv. Number of Uniform Strain Cycles, N

Value	Parameter
5619.60	Ground Surface Elevation at time of CPT (ft amsl)
5626.65	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pl
3.50	Thickness of Water Storage/Rooting Zone (ft)
4.00	Thickness of High Compaction Layer (ft)
-0.95	Thickness of Random/Platform Fill on top of existing interim cover (ft)
812.44	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5590.40	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Bottom of Layer (ft)	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)	Pressure at Bottom of Layer (tsf)	Equil Pore Pressure at Midpoint of Layer (tsf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 2E1

Data File: 13-52106_SP2E1-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Da

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

5613.10	Water surface elevation during CPT investigation (ft a
5611.67	Water surface elevation at t_0 (ft amsl)
5595.46	Water surface elevation at t_1 (ft amsl)
5590.46	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Earth
7.51	Equiv. Number of Uniform Strain Cycles, N

5619.95	Ground Surface Elevation at time of CPT (ft amsl)
5630.46	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after plac
3.50	Thickness of Water Storage/Rooting Zone (ft)
4.00	Thickness of High Compaction Layer (ft)
2.51	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1160.95	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5590.46	Elevation of bottom of tailings (liner) (ft amsl)

Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69

Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Parameter
5613.10	Water surface elevation during CPT investigation (ft a
5611.67	Water surface elevation at t_0 (ft amsl)
5595.46	Water surface elevation at t_1 (ft amsl)
5590.46	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Earth
7.51	Equiv. Number of Uniform Strain Cycles, N

Value	Parameter
5619.95	Ground Surface Elevation at time of CPT (ft amsl)
5630.46	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after plac
3.50	Thickness of Water Storage/Rooting Zone (ft)
4.00	Thickness of High Compaction Layer (ft)
2.51	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1160.95	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5590.46	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Bottom of Layer (ft)	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)	Pressure at Bottom of Layer (tsf)	Equil Pore Pressure at Midpoint of Layer (tsf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 3-1S

Data File:	13-52106_SP3-1S-BSC-CPT
Location:	White Mesa 2013 CPT Investigation
..\..\..\6.2.3 Field Data\2013 Field Investigation\Conetec Da	

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

5608.00	Water surface elevation during CPT investigation (ft
5604.28	Water surface elevation at t_0 (ft amsl)
5595.59	Water surface elevation at t_1 (ft amsl)
5590.59	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Eart
7.51	Equiv. Number of Uniform Strain Cycles, N

5612.56	Ground Surface Elevation at time of CPT (ft amsl)
5620.47	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pl
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
0.41	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
887.10	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5590.59	Elevation of bottom of tailings (liner) (ft amsl)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 3-2C

Data File: 13-52106_SP3-2C-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Dat

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)

Parameter	Value
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69

Youd, et al (2001)

Parameter	Value
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Parameter
5605.30	Water surface elevation during CPT investigation (ft
5602.54	Water surface elevation at t_0 (ft amsl)
5591.64	Water surface elevation at t_1 (ft amsl)
5586.64	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Earth
7.51	Equiv. Number of Uniform Strain Cycles, N

Value	Parameter
5610.82	Ground Surface Elevation at time of CPT (ft amsl)
5621.51	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after place
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
3.19	Thickness of Random/Platform Fill Layer on top of existing interim cover (ft)
1167.12	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5586.64	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Bottom of Layer (ft)	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)	Pressure at Bottom (tsf)	Equil Pore Pressure at Midpoint of Layer (tsf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 3-2C

Data File: 13-52106_SP3-2C-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3 Field Data\2013 Field Investigation\Conetec Data

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69

Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

5605.30	Water surface elevation during CPT investigation (ft amsl)
5602.54	Water surface elevation at t_0 (ft amsl)
5591.64	Water surface elevation at t_1 (ft amsl)
5586.64	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Earthquake
7.51	Equiv. Number of Uniform Strain Cycles, N

5610.82	Ground Surface Elevation at time of CPT (ft amsl)
5621.51	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after placement
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
3.19	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1167.12	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5586.64	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)		Elev. At Midpoint of Layer (ft)	Bottom of Layer (ft)	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)	Pressure at Bottom of Layer (tsf)	Equil Pore Pressure at Midpoint of Layer (tsf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 3-3S

Data File: 13-52106_SP3-3S-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3 Field Data\2013 Field Investigation\Conetec Data

Legend:
- Tailings Sands
- Tailings Sand-Slimes
- Tailings Slimes
- Interim Cover
- Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69

Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

5605.60	Water surface elevation during CPT investigation (ft amsl)
5601.35	Water surface elevation at t_0 (ft amsl)
5582.14	Water surface elevation at t_1 (ft amsl)
5577.14	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Ear
7.51	Equiv. Number of Uniform Strain Cycles, N

5609.63	Ground Surface Elevation at time of CPT (ft amsl)
5620.49	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pl
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
3.36	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1184.24	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5577.14	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Bottom of Layer (ft)	Thicknes s of Layer (ft)	Unit Weigh t (tcf)	Unit Weight (pcf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)	Pressure at Bottom of Layer (tsf)	Equil Pore Pressure at Midpoint of Layer (tsf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 3-3S

Data File: 13-52106_SP3-3S-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Dat

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Description
5605.60	Water surface elevation during CPT investigation (ft amsl)
5601.35	Water surface elevation at t_0 (ft amsl)
5582.14	Water surface elevation at t_1 (ft amsl)
5577.14	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Ear
7.51	Equiv. Number of Uniform Strain Cycles, N

Value	Description
5609.63	Ground Surface Elevation at time of CPT (ft amsl)
5620.49	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pl
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
3.36	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1184.24	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5577.14	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Bottom of Layer (ft)	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)	Pressure at Bottom of Layer (tsf)	Equil Pore Pressure at Midpoint of Layer (tsf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 3-4N

Data File: 13-52106_SP3-4N-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Da

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Parameter
5606.00	Water surface elevation during CPT investigation (ft
5600.42	Water surface elevation at t_0 (ft amsl)
5583.71	Water surface elevation at t_1 (ft amsl)
5578.71	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Ear
7.51	Equiv. Number of Uniform Strain Cycles, N
5608.70	Ground Surface Elevation at time of CPT (ft amsl)
5623.35	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pl
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
7.15	Thickness of Random/Platform Fill on top of existing interim cover (ft)
1565.99	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5578.71	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Bottom of Layer (ft)	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)	Pressure at Bottom of Layer (tsf)	Equil Pore Pressure at Midpoint of Layer (tsf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 3-6N

Data File: 13-52106_SP3-6N-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Da

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69
Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

5604.20	Water surface elevation during CPT investigation (ft a
5599.16	Water surface elevation at t_0 (ft amsl)
5590.44	Water surface elevation at t_1 (ft amsl)
5585.44	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Earth
7.51	Equiv. Number of Uniform Strain Cycles, N

5607.44	Ground Surface Elevation at time of CPT (ft amsl)
5623.62	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pla
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
8.68	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1720.10	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5585.44	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Bottom of Layer (ft)	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)	Pressure at Bottom of Layer (tsf)	Equil Pore Pressure at Midpoint of Layer (tsf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)

WHITE MESA TAILINGS REPOSITORY LIQUEFACTION AND SEISMIC SETTLEMENT ANALYSES - 3-8S

Data File: 13-52106_SP3-8S-BSC-CPT
Location: White Mesa 2013 CPT Investigation
..\..\..\6.2.3_Field Data\2013 Field Investigation\Conetec Data

Legend: Tailings Sands; Tailings Sand-Slimes; Tailings Slimes; Interim Cover; Cells Requiring User Input/Manipulation

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69

Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

5603.50	Water surface elevation during CPT investigation (ft amsl)
5600.42	Water surface elevation at t_0 (ft amsl)
5590.63	Water surface elevation at t_1 (ft amsl)
5585.63	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ratio, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Earthq
7.51	Equiv. Number of Uniform Strain Cycles, N

5608.70	Ground Surface Elevation at time of CPT (ft amsl)
5620.45	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after pla
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
4.25	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1273.89	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5585.63	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)	Elev. At Midpoint of Layer (ft)	Bottom of Layer (ft)	Thickness of Layer (ft)	Unit Weight (tcf)	Unit Weight (pcf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)	Pressure at Bottom of Layer (tsf)	Equil Pore Pressure at Midpoint of Layer (tsf)	Stress at Bottom of Layer (tsf)	Stress at Midpoint of Layer (tsf)

Idriss and Boulanger (2008)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	1.69

Youd, et al (2001)	
Max. Horiz. Acceleration, Amax/g:	0.15
Earthquake Moment Magnitude, M:	5.5
Magnitude Scaling Factor, MSF:	2.21

Value	Description
5603.50	Water surface elevation during CPT investigation (ft amsl)
5600.42	Water surface elevation at t_0 (ft amsl)
5590.63	Water surface elevation at t_1 (ft amsl)
5585.63	Water surface elevation at t_2 (ft amsl)
1.44	Scaling Factor for stress ration, r_m
0.47	Volumetric Strain Ratio for Site-Specific Design Earthquake
7.51	Equiv. Number of Uniform Strain Cycles, N

Value	Description
5608.70	Ground Surface Elevation at time of CPT (ft amsl)
5620.45	Ground Surface Elevation Immediately after Placement of Final Cover (ft amsl)
0.50	Thickness of Erosion Protection Layer (rock mulch/topsoils) Immediately after placement
3.50	Thickness of Water Storage/Rooting Zone (ft)
3.50	Thickness of High Compaction Layer (ft)
4.25	Thickness of Random/Platform Fill on on top of existing interim cover (ft)
1273.89	Additional Stress due to Final Cover Placement, $\Delta\sigma_{FC}$ (psf)
5585.63	Elevation of bottom of tailings (liner) (ft amsl)

FINAL COVER	Elev. at Top of Layer (ft)		Elev.
