February 27, 2018

Subject: Project update for Phase 2 Jordan River Dissolved Oxygen TMDL.

Dear Jordan River Stakeholder,

The Utah Division of Water Quality (DWQ) has decided to delay completion of Phase 2 of the Jordan River Dissolved Oxygen Total Maximum Daily Load (TMDL) to incorporate an updated water quality model currently in development by researchers in the University of Utah’s Civil and Environmental Engineering Department. Phase 1 of the TMDL was completed and approved by the Environmental Protection Agency (EPA) in June of 2013. Since completion of Phase 1, additional data has been collected and summarized in a research memorandum that will be distributed by December 2017.

The development of a new water quality model by the University of Utah is the result of an EPA grant to develop a basin-wide water quality and quantity model of the Jordan River watershed. This effort will use the dynamic Water Quality Analysis Simulation (WASP) model, that will allow us to: confirm organic matter as the primary pollutant of concern; explore linkages between nutrient loading and organic matter; refine pollutant loading estimates; assign wasteload allocations (WLAs) and load allocations to sources; and link pollutant sources to the dissolved oxygen impairment. The completion date for the TMDL is contingent on validation of the water quality model but at this time we estimate that the TMDL will be completed by 2020.

While the model is under development we will focus on characterizing storm water pollutant loads and promoting implementation of best management practices. To incentivize implementation, reductions in storm water loads obtained prior to WLA development will be credited to permitted MS4s and POTWs. In other words, the permittee will be credited in the future for reductions that occur now. To obtain this credit the MS4 will be responsible for monitoring storm water, documenting load reductions, and providing this information to DWQ. Permitted MS4s are also strongly encouraged to conduct their own storm water monitoring which is critical for assigning appropriate and equitable wasteload allocations. In both efforts, DWQ will provide technical and financial assistance to the extent possible.
If you have any questions or concerns please contact Lucy Parham at 801.536.4332 or lparham@utah.gov.

Sincerely,

Erica Brown Gaddis, PhD
Director

Subject: Project update for Phase 2 Jordan River Dissolved Oxygen TMDL.

Dear Mr. Munger,

The Utah Division of Water Quality (DWQ) has decided to delay completion of Phase 2 of the Jordan River Dissolved Oxygen Total Maximum Daily Load (TMDL) to incorporate an updated water quality model currently in development by researchers in the University of Utah’s Civil and Environmental Engineering Department. Phase 1 of the TMDL was completed and approved by the Environmental Protection Agency (EPA) in June of 2013. Since completion of Phase 1, additional data has been collected and summarized in a research memorandum that will be distributed by December 2017.

The development of a new water quality model by the University of Utah is the result of an EPA grant to develop a basin-wide water quality and quantity model of the Jordan River watershed. This effort will use the dynamic Water Quality Analysis Simulation (WASP) model, that will allow us to: confirm organic matter as the primary pollutant of concern; explore linkages between nutrient loading and organic matter; refine pollutant loading estimates; assign wasteload allocations (WLAs) and load allocations to sources; and link pollutant sources to the dissolved oxygen impairment. The completion date for the TMDL is contingent on validation of the water quality model but at this time we estimate that the TMDL will be completed by 2020.

While the model is under development we will focus on characterizing storm water pollutant loads and promoting implementation of best management practices. To incentivize implementation, reductions in storm water loads obtained prior to WLA development will be credited to permitted MS4s and POTWs. In other words, the permittee will be credited in the future for reductions that occur now. To obtain this credit the MS4 will be responsible for monitoring storm water, documenting load reductions, and providing this information to DWQ. Permitted MS4s are also
strongly encouraged to conduct their own storm water monitoring which is critical for assigning appropriate and equitable wasteload allocations. In both efforts, DWQ will provide technical and financial assistance to the extent possible.

If you have any questions or concerns please contact Lucy Parham at 801.536.4332 or lparham@utah.gov.

Sincerely,
