

## Utah Lake Water Quality Study

### ULWQS Management Goals: Science Panel Responses to Steering Committee Questions

November 13, 2020

The Science Panel (SP), commissioned by the Utah Lake Water Quality Study (ULWQS) Steering Committee (SC), is providing this document in response to the SC's request to evaluate and answer a series of questions related to the ongoing effort to develop management goals for Utah Lake. The questions were presented to the SP during Science Panel Call #16 on October 21, 2020. Following the call, the SP worked to reference the content of existing work products in addition to available Utah Lake-specific data and literature to inform response development.

The SP is drawing upon existing work products and data to determine the relevancy of the goals, measures, and targets in the process of developing numeric nutrient criteria (NNC) for Utah Lake. Specifically, the following SP work products and information were referenced in the process of responding to the questions from the SC:

- ***ULWQS Conceptual Model Report*** (SP and SC approved) – The models in the Conceptual Model Report visually demonstrate the SP's understanding of the causal pathways that connect nutrient sources to designated beneficial uses, the expected relationships between variables, and the modifying factors. The conceptual models specifically include the management goals and measures defined by the SC, and describe how they are responsive to nutrient inputs;
- ***ULWQS NNC Technical Framework*** (Draft) – The Technical Framework defines the expected stressor response variables to be used for developing NNC in addition to the associated empirical and mechanistic modeling methods;
- ***ULWQS Data Analysis Report*** (Draft) – The Data Analysis Report describes relationships between important nutrient-related variables. This analysis was specifically designed to address the Initial High Level Charge Questions developed by the SC to the SP;
- ***ULWQS Strategic Research Plan (SRP)*** (SP approved, SC review pending) – The SRP identifies knowledge gaps that limit the SP's ability to develop responses to the Initial Charge and prioritizes research activities to address the gaps;
- ***Assessment of Utah Lake nutrient and HAB data*** – The Utah Lake chemistry and harmful algal bloom dataset was evaluated to inform answers to questions 2e and 2f; and
- ***Literature from similar lake systems*** was evaluated to identify analytical methods and to provide context for our responses to questions.

#### **Question 1. Assessment of the relevance of the management goals to the ULWQS purpose.**

The SP views the development of management goals as the primary responsibility of the SC. As a result, to answer question 1 we first assessed the responsiveness and quantifiability of individual measures and targets to nutrient interactions in the lake as described in our evaluation of questions 2, 3, 4 and 5. Based on the level of responsiveness of individual measures, we then assessed the relevance of each goal. We also included an evaluation of the quantifiability of each goal, given the evaluation of the component measures for each management goal. Through this evaluation we determined that most of the management goals are relevant to the project purpose, noting that some are less directly relevant than others (See Attachment A, pages 3-4).

**Question 2, 3, 4, and 5 (excluding 2e and 2f). Assessment of measures' and targets' responsiveness to nutrients, and evaluation of available data and assessment methods.**

To evaluate questions 2, 3, 4, and 5 we reviewed existing SP products (as described previously) to identify relevant data, determine data resolution, and draw upon previous SP findings to determine responsiveness of each measure to nutrients. We also considered both our ability to quantify future targets and consider the most appropriate methods for evaluating current conditions.

Our responses for each question are presented in Attachment A, pages 5-13. Significant findings include:

- Are measures responsive to nutrients? (question 2)
  - The majority of the measures are known to be defensibly responsive to nutrients. Exceptions include: annual visitation to Utah Lake (likely responsive), measures from recreation survey to assess user experiences related to water quality (likely responsive), carp population density (not responsive), and percent change in non-algal turbidity associated with carp bioturbation (not responsive).
- Are measures readily quantified with existing information? (question 2a)
  - Many of the measures can be readily quantified using existing data. Exceptions include: cylindrospermopsin concentration, saxitoxin concentration, annual visitation to Utah Lake, measures from recreation survey to assess user experiences related to water quality, fish tissue algal toxin concentrations, mollusk diversity/abundance, percent change in non-algal turbidity associated with carp bioturbation, percent change in macrophyte density and distribution, percent cover of *Phragmites* on Utah Lake shoreline, percent cover of emergent and submergent macrophytes in littoral waterfowl and shorebird habitat areas, maximum # of days at each of littoral habitat exceeding TBD HAB threshold, and the maximum percent of littoral habitat area exceeding TBD HAB threshold..
- What additional efforts are required to quantify measures? (questions 2b, 2c & 2d)
  - If a measure can be quantified with existing information (question 2a), then additional efforts are not required to address the specific measure. This results in a not applicable (NA) result for questions 2b, 2c and 2d.
  - If a measure cannot be quantified with existing information, then additional efforts associated with SP analyses, WQ modeling, studies, or monitoring are required. See Attachment A for the proposed efforts (2b, 2c and 2d) required to quantify the specific measures.
- What measures are infeasible to assess or very difficult to develop targets? (question 3)
  - Most measures can be assessed, and targets can be developed. Exceptions include: annual visitation to Utah Lake (difficult), measures from recreation survey to assess user experiences related to water quality (difficult), carp population density (not related to nutrients), and percent change in non-algal turbidity associated with carp bioturbation (not related to nutrients).
  - The caveat to question 3 is that the ULWQS effort may not have the funding nor the time to quantify each and every measure provided by the SC in Attachment A. Careful consideration of the measures relevant to the development of in-lake numeric nutrient criteria is required to successfully move the ULWQS effort forward.

- How to calculate current conditions and predict future scenarios? (questions 4, 4a and 4b)
  - See Attachment A.
- What additional measures should be considered? (question 5)
  - See Attachment A for suggestions to improve quantification and reduce uncertainty for the SC proposed measures.

**Question 2e and 2f. Relationships between nutrients and cyanobacterial density and between cyanobacterial density and toxin concentrations in Utah Lake.**

Tetra Tech provided a technical memo under the direction of the SP to explore preliminary relationships between nutrients, cyanobacteria cell counts, and cyanotoxins to inform questions 2e and 2f. After comments and discussion regarding additional analyses and the exploration of various covariates, the SP decided that additional effort is warranted to answer questions 2e and 2f. Based on the feedback provided by the SP members, we intend to continue investigating these questions in the ongoing ULWQS Data Analysis Report in more detail. In addition, the Bioassay study commissioned by the SP is investigating phytoplankton responses to increased and reduced nutrient concentrations. This study will be finalized in the near future and is expected to provide Utah Lake-specific information relevant to questions 2e and 2f. These questions are instrumental to developing numeric nutrient criteria to manage HABs in Utah Lake and additional exploration will improve our understanding and certainty with these relationships.

Sincerely,

ULWQS Science Panel

- Janice Brahney, Utah State University
- Soren Brothers, Utah State University\*
- Greg Carling, Brigham Young University
- Mitch Hogsett, Forsgren Associates, Science Panel Chair
- Ryan King, Baylor University
- James Martin, Mississippi State University
- Michael Mills, June Sucker Recovery Program
- Hans Paerl, University of North Carolina\*

\* Indicated they could live with the package

NOTE: the following two members approved the Table on the November 4 call, however have not yet responded to the request for final review of the package:

- Michael Brett, University of Washington
- Theron Miller, Wasatch Front Water Quality Council

# Attachment A: Science Panel Evaluation of Steering Committee Questions (Not Including 2e and 2f)

## Steering Committee Questions to the Science Panel

The SP can provide important scientific feedback on defensible assessment endpoints, measures, targets and target development to evaluate progress towards management goals. Important questions to convey to the SP with the table include:

### Management Goals

1. Please share your thoughts on the direct relevancy of the Management Goals to the ULWQS purpose of developing in-lake nitrogen and phosphorus criteria.

### Measures and Targets

2. Are these measures defensibly responsive to nutrients?
  - a) Which of these measures can be readily quantified using existing information?
  - b) Which measures and targets will be quantified by ongoing Science Panel analyses or the existing water quality model and therefore available for consideration of nutrient reduction scenarios?
  - c) Which of the measures may require additional studies (monitoring, modeling, etc.) and what are the requirements for that?
  - d) Of those that might not be quantifiable, are there other approaches (modeling or empirical) by which targets can be derived?
  - e) Is there a direct correlation between cyanobacteria cell counts and nutrients?
  - f) Is there a relationship between cyanobacteria cell counts and toxins?
    - Specifically, can and how do you predict change in toxin concentrations under different scenarios?
    - The EPA 2019 document (Recommended Human Health Recreational Ambient Water Quality Criteria or Swimming Advisories for Microcystins and Cylindrospermopsin) is read by some to say no relationship between toxins and recreational use, is that your understanding?
3. Are there measures that will be infeasible to assess or for which target development will be difficult?
4. What methods should be used to calculate current conditions for each measure?
  - a) Can these methods be applied using modeling (empirical or mechanistic) to predict change under future scenarios?
  - b) How should we group monitoring sites in evaluating current and future conditions?

### Other considerations

5. Are there potential measures or targets not included that should be considered by the SC?

## Responses to Steering Committee Questions

### Steering Committee Question 1.

Table 1. Assessment of Steering Committee Question 1.

| Management Goal   | Assessment Endpoint                                 | Please share your thoughts on the direct relevancy of the Management Goals to the ULWQS purpose of developing in-lake nitrogen and phosphorus criteria? |                                     |  |
|---|---|---|-------------------------------------|--|
|   |   | Relevant?   | Currently Quantifiable?             | Overall  |
| <b>2A. Primary contact recreation use (human health, Recreation experience, Lake aesthetics)</b>                        |   |   |                                     |  |
| Harmful algal blooms (HAB) will not create toxins that threaten public health.  | Algal toxin concentrations                          | Yes   | Yes                                 | This goal is directly relevant to nutrient criteria development, data for assessment endpoint measures (except cylindrospermopsin) are readily available and can be quantified.  |
| HAB occurrence is limited in spatial extent and infrequent to support robust recreational industry and community.       | Magnitude, frequency, and duration of algal blooms. | Yes   | Yes                                 | This goal is directly relevant to nutrient criteria development, data for assessment endpoint measures are readily available, and can be quantified.   |
| Improve submersible recreation (swimming, paddle boarding, water skiing, etc.) experience.                              | Magnitude, frequency, and duration of algal blooms. | Yes   | Yes                                 | This goal is directly relevant to nutrient criteria development, data for assessment endpoint measures are readily available, and can be quantified.   |
| Swimming beaches and shoreline access locations are open all summer without nuisance algae or public health advisories. | Magnitude, frequency, and duration of algal blooms. | Yes   | Yes                                 | This goal is directly relevant to nutrient criteria development, data for assessment endpoint measures are readily available, and can be quantified.   |
| Recreation water quality standards are supported  | Support of 2A Recreational Use Standards            | Yes   | Unknown since these are narratives. | Science Panel presumes that numeric targets developed for other category 2A management goals are already being used to interpret the narrative water quality standards.  |
| Increase recreational opportunities and experiences.  | Lake visitation and satisfaction statistics.        | Likely  | No                                  | This goal is likely relevant to nutrient criteria development in that it is important to understand the effect of nutrient pollution on recreation. However, visitation targets do not exist, visitation data are limited to one location, and relationships of algal indicators to visitation measures have yet to be quantified.     |
| Improve public perception of Utah Lake water quality.   | Lake visitation and satisfaction statistics.        | Likely  | No                                  | This goal is likely relevant to nutrient criteria development in that it is important to understand the effect of nutrient pollution on recreational use perception, but user perception data or targets have still to be developed. This measure has shown relevance and utility in other lake nutrient criteria development efforts. |
| Sport fish are safe for human consumption.  | Fish tissue algal toxin concentrations.             | Yes   | No                                  | This goal is directly relevant to nutrient criteria development. However, data are not available, and therefore this measure cannot currently be quantified.   |
| <b>3B. Warm water fishery use</b>   |   |   |                                     |  |
| Warm water fishery is robust and healthy.   | Water quality conditions                            | Yes   | Yes                                 | This goal is directly relevant to nutrient criteria development, data for water quality condition assessment endpoint measures are readily available and can be quantified.  |
|   | Food abundance and diversity                        | Yes   | Yes, but limited                    | This goal is directly relevant to nutrient criteria development, data for food (zooplankton, macroinvertebrate, and mollusk) abundance and diversity assessment endpoint measures are also available and can be quantified but are more limited.   |

| Management Goal   | Assessment Endpoint  | Please share your thoughts on the direct relevancy of the Management Goals to the ULWQS purpose of developing in-lake nitrogen and phosphorus criteria? |                         |   |
|---|--|---|-------------------------|---|
|   |  | Relevant?   | Currently Quantifiable? | Overall   |
| HAB toxins do not cause fish mortality.   | Algal toxin concentrations   | Yes   | Yes                     | This goal is directly relevant to nutrient criteria development, data for assessment endpoint measures (except cylindrospermopsin) are readily available and can be quantified.   |
| Warm water fishery can support reproductive populations of June Sucker.   | Water quality conditions   | Yes   | Yes                     | This goal is directly relevant to nutrient criteria development, data for assessment endpoint measures are readily available, and can be quantified   |
| Macrophyte habitat can support June sucker recovery and early life stages of other ecologically or recreationally important fish species. | Macrophyte abundance and distribution in Provo Bay, Utah Lake Littoral Zones, and Provo River delta.       | Yes   | Yes, but limited        | This goal is directly relevant to nutrient criteria development. Data for assessment endpoint measures are available, and can be quantified, but are relatively limited.  |
| Carp population does not inhibit June sucker recovery.  | Carp density and water quality indicators related to carp activity.  | Mixed   | Mixed                   | Carp density and change in turbidity associated with carp bioturbation are not considered responsive or are of unknown responsiveness to nutrients so are of limited relevance to nutrient criteria development, but percent change in macrophyte density and distribution are responsive to nutrient and are directly relevant to nutrient criteria development. Data on carp density are available, but data on carp-induced non-algal turbidity and macrophyte density and distribution across the lake are not; so only carp density can be readily quantified, even though it is of limited relevance. |
| <b>3D. Waterfowl, shorebirds, and other water-oriented wildlife</b>   |  |   |                         |   |
| Sufficient percentage cover of native and desirable nonnative littoral plant species.   | Nonnative plant abundance, diversity, and distribution. Macrophyte abundance, diversity, and distribution. | Yes   | No                      | This goal is directly relevant to nutrient criteria development, however data for assessment endpoint measures are not readily available and cannot be readily quantified.  |
| Macroinvertebrates provide a diverse and sufficient food source to birds that use the open water and shorelines of Utah Lake.             | Invertebrate abundance, diversity, and distribution.   | Yes   | Yes, but limited        | This goal is directly relevant to nutrient criteria development, data for invertebrate abundance, diversity, and distribution assessment endpoint measures are also available and can be quantified but are more limited.   |
| HAB toxins do not threaten waterfowl and shorebirds and do not cause bird mortality.  | Algal toxin concentrations.  | Yes   | Yes                     | This goal is directly relevant to nutrient criteria development, data for assessment endpoint measures (except cylindrospermopsin) are readily available and can be quantified.   |
| HAB spatial and temporal extent supportive of healthy waterfowl and shorebird habitat.  | Harmful algal bloom magnitude and duration.  | Yes   | Yes                     | This goal is directly relevant to nutrient criteria development, data for assessment endpoint measures are readily available, and can be quantified   |
| <b>4. Agricultural Water Use</b>  |  |   |                         |   |
| Water used to irrigate crops will not present health risk.  | Algal toxin concentrations.  | Yes   | Yes                     | This goal is directly relevant to nutrient criteria development, data for assessment endpoint measures (except cylindrospermopsin) are readily available and can be quantified.   |
| Water used to water livestock will not pose health risk to animals.   | Algal toxin concentrations.  | Yes   | Yes                     | This goal is directly relevant to nutrient criteria development, data for assessment endpoint measures (except cylindrospermopsin) are readily available and can be quantified.   |
| Water used for secondary water does not clog or impede irrigation systems.  | Algal and cyanobacteria density/biomass.   | Yes   | Yes                     | This goal is directly relevant to nutrient criteria development, data for assessment endpoint measures are readily available, and can be quantified.  |
